ABSTRACT (Continue on reverse if necessary and identify by block number) As part of the USAF Installation Restoration Program (IRP), five sites on Mountain Home Air Force Base, Idaho, were investigated to determine the presence of hazardous material contamination resulting from past handling and disposal practices. The five sites investigated were the Lagoon Landfill, "B" Street Landfill, the fire training area, a fuel hydrant system leak area, and the Entomology Shop yard. Investigations consisted of monitor well installations at the two landfills and soil borings at the other three sites. Ground water and soil samples were subjected to chemical analyses for screening level parameters. Indication of low-level contamination was found in the ground water below both landfills and in the soils of the fire training area. Additional sampling and analyses are recommended to define the nature of the contamination at those sites.

## PREFACE

As part of the U.S. Air Force Installation Restoration Program (IRP), investigations were undertaken at five sites on Mountain Home Air Force Base, Idaho, to determine whether hazardous material contamination is present. This report, prepared by Dames & Moore under Contract No. F33615-83-D-4002, Order 0009, presents the results of the Phase II, Stage 1 IRP investigations. The period of work reported on herein was January through September 1984. The field investigations were directed by Dr. Kenneth J. Stimpfl and were undertaken under the technical management of Mr. George W. Condrat. Field work was undertaken by Mr. Steven B. Johnson. Maj. George New and Dr. John Yu, Technical Services Division, USAF Occupational and Environmental Health Laboratory (OEHL), were the technical monitors.

## SUMMARY

Mountain Home Air Force Base (AFB) is located approximately 10 miles southwest of Mountain Home, Idaho. It is situated on the Mountain Home Plateau, which is a rolling upland plain underlain by over 10,000 feet of volcanic and sedimentary rock. The base has been in operation since 1943 and currently houses tactical fighter squadrons that use the F-111A and the EF-111A aircraft.

The Phase II, Stage 1 field evaluation of the Installation Restoration Program (IRP) consisted of investigations at the following five sites:

- Site 1 - Lagoon landfill,
- Site 2 - "B" Street landfill,
- Site 8 - Existing fire department training area,
- Site 11 - Fuel hydrant system leak/spill area, and
- Site 12 - Entomology shop yard.

The field investigation consisted of the following activities:

- o Installation and sampling of a monitor well at Site 1 and Site 2;
- o Sampling of base wells MH-1, MH-3, MH-4, MH-5, MH-6, and MH-7, and the east and west wastewater lagoons at Site 1;
- o Drilling and sampling three borings at Site 8;
- o Drilling and sampling three borings at Site 11; and
- o Drilling and sampling three borings at Site 12.

The ground water samples were analyzed for 16 pesticides, 5 trace metals, oil and grease, phenol, total organic carbon (TOC), and total organic halogens (TOX). The soil samples from Sites 8 and 11 were analyzed for moisture content, TOX, TOC, oil and grease, phenol, and lead. The soil samples from Site 12 were analyzed for moisture content and 16 pesticides by EP toxicity test extraction.

Ground water is available from the Bruneau and Glens Ferry Formations beneath the site, although all the base wells and monitor wells are completed in the Bruneau Formation. Both formations contain highly permeable layers of fractured and porous basalt and coarse sand and gravel. The formations behave as a single aquifer in which ground water is present under unconfined conditions. Ground water quality is suitable for most purposes, although the concentrations of total dissolved solids have been increasing in water from base wells MH-2, MH-3, and MH-4 since about 1960 and had increased in old base well MH-1 until it was replaced in 1974. The source of the dissolved solids is either upward flow from the Glens Ferry Formation, which contains slightly lower quality water than the Bruneau Formation, or downward migration of contaminants such as nitrate, chlorides, and sulfates. Regional ground water flow is generally toward the south, where it eventually discharges into the Snake River.

The ground water analyses showed evidence of organic ground water contamination based on TOX concentrations in one base well and both monitor well samples. Halogenated organic compounds (TOX) are present in ground water beneath the entire base, but levels in the range of 0.059 to 0.086 milligrams per liter (mg/L) are believed to represent background levels. In contrast, TOC concentrations were too low to interpret them conclusively as either background or contaminated conditions. Although there is evidence that the waste disposal sites are the sources, it is possible that contaminants also originate from off-site sources. Insignificant levels of contaminants were found in soil samples from Site 11, where several thousand gallons of jet fuel were spilled in the late 1950s. Relatively high concentrations of TOX, TOC, and oil and grease were detected at Site 8, the fire department training area. The greatest contamination was within the bermed area in which jet fuel is pooled before it is burned for training exercises. Seven of the 16 pesticides included in the analyses were detected in EP toxicity test extracts of soil samples from Site 12, adjacent to the entomology shop building. Dieldrin was found in all the samples, and DDD was found in all but one of the samples. The remaining 5 pesticides were detected in 1 or 2 samples each. Only samples from the upper 1 foot of soil were analyzed, so it is not known how deep the pesticides are distributed. Similarly, the areal extent cannot be estimated based on Phase II, Stage 1 results. The pesticide concentrations in the EP toxicity test extracts were very low.

The Phase II, Stage 1 conclusions are as follows:

1. Evidence of ground water contamination was identified by the presence of TOX (total organic halogens) in one base well and one monitor well. The concentrations in both were 0.12 mg/L. No pesticides were detected in the monitor well samples, so the organic halogens may be due to solvents, herbicides, or other organic contaminants. TOC (total organic carbon) concentrations were too low to conclusively indicate background or contaminated conditions. The magnitude and associated health risk cannot be assessed until the individual compounds contributing to TOX are known.
2. High TOX concentrations and seven pesticides were detected in the lagoon samples, indicating that the lagoons may be a source of the ground water contaminants. The highest concentrations of TOX in the ground water samples were 0.12 mg/L from Monitor Well 1 (MW-1), which was completed beneath the lagoon landfill, and 0.12 mg/L from base well MH-3.
3. No significant contamination was found at Site 11.
4. Evidence of contamination was identified at Site 8; however, the depth of contamination could not be determined from Phase II, Stage 1 results.

Because hazardous wastes may be migrating from the site through infiltration of jet fuel, there is a potential that it may be a source of organic contaminants that could eventually reach the ground water.

5. Soil adjacent to the entomology shop (Site 12) has been contaminated with pesticides to a depth of at least 1 foot, although the areal extent could not be estimated from Phase II, Stage 1 results. Based on chemical analyses of EP toxicity test extractions of soil samples, the contamination is extremely low and does not warrant further investigation.

The following summarizes our recommendations and the rationale for further activities:

Sites	Recommended Action	Rationale
1 and 2, base wells	Develop an accurate ground water elevation map by surveying elevation and location of base wells and monitor wells. Based on the results of the survey, determine whether Monitor Well 2 (MW-2) is upgradient or downgradient of the "B" Street landfill. If MW-2 is downgradient, no further work should be done at Site 2. If MW-2 is determined to be upgradient of the landfill, three additional monitor wells should be installed downgradient. If the results of the survey do not clearly indicate whether MW-2 is upgradient or downgradient, install one well upgradient and three wells downgradient as defined by the ground water elevation map. At Site 1, install four monitor wells. Place one well upgradient and three wells downgradient. Sample the eight new wells; operating base wells MH-1, MH-3, and MH-5; MW-1 and MW-2 (if needed); and the two lagoons; measure pH, specific conductance, and temperature; and analyze the samples for USEPA 601 and 602 parameters, major cations and anions, and cadmium.	To characterize the organic and inorganic content of ground water beneath the base and define the ground water flow system.

Sites	Recommended Action	Rationale
8	Drill and sample one background boring and two additional borings to depths at which soil samples do not emit organic vapors. Analyze soil samples for volatile and semivolatile organics, oil and grease, and moisture content.	To estimate the vertical extent of contamination and determine whether the site is a potential source of ground water contamination.

## **I. INTRODUCTION**

### **A. BACKGROUND**

The Department of Defense (DOD) initiated the Installation Restoration Program (IRP) in 1976 to investigate and mitigate any environmental contamination which may be present at DOD facilities as a result of handling or disposing hazardous materials. IRP was revised in 1981 and reissued as the Defense Environmental Quality Program Policy Memorandum (DEQPPM) 81-5. The Air Force implemented DEQPPM 81-5 in 1982 as a four-phased program:

- Phase I    Problem Identification/Records Search
- Phase II    Problem Confirmation and Quantification
  - o    Presurvey
  - o    Field Evaluation - several stages as warranted
- Phase III    Technology Base Development
- Phase IV    Corrective Action

Phase I was completed by CH2M Hill (1983), and the Phase II Presurvey was completed by Dames & Moore (1983). Dames & Moore has been retained by the Air Force under Contract Number F33615-83-D-4002 to conduct Phase II, Stage 1, Field Evaluation, at Mountain Home Air Force Base (AFB) near Mountain Home, Idaho.

This report presents the results of Dames & Moore's field and laboratory investigations in the vicinity of waste disposal and hazardous material handling areas at Mountain Home AFB.

### **B. PURPOSE AND SCOPE**

The purposes of the field evaluation portion of Phase II of the IRP were as follows:

1. Determine whether environmental contamination has resulted from material handling or waste disposal practices at Mountain Home AFB;
2. If contamination is found, provide estimates of the magnitude and extent of the contamination; and
3. Identify any additional investigations and their attendant costs necessary to identify the magnitude, extent, and direction of movement of discovered contaminants.

The scope of work as outlined for Phase II, Stage 1 of the IRP consisted of the following activities:

1. Drilling, sampling, and geologically logging one boring to a depth of 402 feet at the lagoon landfill (Site 1) and one boring to a depth of 410 feet in the "B" Street landfill (Site 2).
2. Installing and developing a monitor well in each boring.
3. Sampling the two monitor wells; base wells MH-1, MH-3, MH-4, MH-5, MH-6, and MH-7; and the east and west wastewater lagoons.
4. Analyzing the ground water and lagoon samples for 25 parameters, including trace metals, pesticides, and others.
5. Drilling, soil sampling, and geologically logging three borings at the existing fire department training area (Site 8), three borings at the fuel hydrant system leak/spill area (Site 11) and three borings at the entomology shop yard (Site 12).
6. Analyzing selected soil samples from each site for specific constituents, including total organic halogens (TOX), total organic carbon (TOC), oil and grease, metals, phenols, and pesticides.
7. Preparing this report, which presents our findings and recommendations.

Field work began on 26 March 84 and was completed on 14 April 84.

#### **C. BRIEF HISTORY OF MOUNTAIN HOME AFB AND WASTE DISPOSAL OPERATIONS**

Mountain Home AFB is located about 10 miles southwest of Mountain Home, Idaho (see Plate 1). It was established in 1943 and served as a base for several different bombardment groups until it was deactivated in the fall of 1945. The base served as a Strategic Air Command base between 1948 and 1950 and later between 1953 and 1965. The Tactical Air Command has controlled the base since 1965. The current mission of the base is to develop and maintain tactical fighter squadrons. The principal aircraft flown at the base are the F-111A and the EF-111A.

Hazardous wastes and chemicals have been used and generated at Mountain Home AFB since 1943 for aircraft maintenance and other industrial operations. These activities generated between 20,000 to 40,000 gallons per year of waste oils, fuels, solvents, paints, and paint thinners (CH2M Hill, 1983). Other wastes generated by the base include sanitary sewage and refuse. In the past, the hazardous wastes have been disposed of by one or more of the following methods:

This is a detailed topographic map of the Mountain Home Air Force Base area in Idaho. The map features the following elements:

- Compass Rose:** Located in the top left corner, indicating North.
- Geographical Features:**
  - Mountains/Buttes:** Cinder Cone Butte (3826'), Lockman Butte (3789'), Little Joe Butte (3214'), Dargay Butte (2932').
  - Reservoirs:** Fraser Reservoir, C. J. Strike Reservoir.
  - Waterways:** Snake River, Spring Creek, Mud Lake Creek, Soda Creek, Little Lost Creek, Rattlesnake Creek, Snake River.
  - Other Features:** Crater Rings, Nat. Guard Maneuver Engineering Area, Mountain Home Gunnery Range, Mountain Home Air Force Base (highlighted with a box), Mountain Home McArthur, Power Substation, Rattlesnake Spgs, Flatiron Butte (2829').
- Elevation Contours:** Various contour lines are marked with elevations such as 3115, 3030, 3099, 3027, 3004, 2975, 2980, 3010, 3034, 3050, 3080, 2858, 2455, 5599, 2836, 2927, 2999, 3572, and 3500.
- Roads and Railroads:**
  - Roads:** Highway 30, Highway 26, Highway 51, Highway 20.
  - Railroads:** Mountain Home Railroad, Minner Railroad.
- County Boundaries:** Elmore County, Ada County, Blaine County, and Bannock County are labeled.
- Settlements and Landmarks:** Mountain Home, New Mountain Home, Farm, Ranch, House, Sand dunes, Browns Gulch, and various smaller landmarks like "Cinder Cone" and "Crater Rings".
- Map Scale and Orientation:** The map is oriented with North at the top. A scale bar is present at the bottom left, showing distances in miles (0 to 10).

PLATE I

- o Incineration through fire department training exercises;
- o Dumping at the lagoon landfill or "B" Street landfill; and/or
- o Discharging to the sanitary sewer, road oiling, or collection and removal by a contractor.

Since 1969, the wastes have been collected by a contractor or sent to the Defense Property Disposal Office for sale.

#### D. DESCRIPTION OF SITES

CH2M Hill (1983) identified 17 sites where hazardous materials had been handled, spilled, or disposed of within Mountain Home AFB. The following sites received the highest ratings for environmental impact and were investigated during Phase II, Stage 1:

1. Lagoon landfill (Site 1),
2. "B" Street landfill (Site 2),
3. Existing fire department training area (Site 8),
4. Fuel hydrant system leak/spill area (Site 11), and
5. Entomology shop yard (Site 12).

The sites investigated during Phase II, Stage 1 are shown in Plate 2, and each site is described below.

##### 1. Site 1 - Lagoon Landfill

The lagoon landfill is located on the west side of the base at the site of the current wastewater lagoons. This site served as the main base sanitary landfill between 1952 and 1956, and the wastewater lagoons were constructed in 1961 and 1962. The landfill received general refuse, which was burned, and about six drums per month of mineral oils, hydraulic fluids, engine oils, and solvents such as trichloroethylene and carbon tetrachloride. Their potential for environmental impact is considered high due to the possibility for infiltration from the wastewater lagoons to leach hazardous contaminants from the underlying landfill.

**Dames & Moore**

**PLATE 2**

The wastewater treatment system now located at Site 1 consists of four oxidation lagoons occupying a total of 72.8 acres with an average water depth of 3.5 to 4 feet. Currently, daily flow to the treatment system averages about 800,000 gallons of sewage. Oil/water separators collect waste oils and lubricants from the industrial shop discharges. Water and sediments from the oil/water separators are disposed of at the "B" Street landfill (Site 2). Disposal of the wastewater effluent is by evaporation and percolation from the lagoons. Under normal conditions, no effluent leaves the base, so no National Pollutant Discharge Elimination System (NPDES) permit is required. Overflow from the lagoons is captured in two infiltration ponds. According to CH2M Hill (1983), measurements of biochemical oxygen demand (BOD<sub>5</sub>), nitrate, nitrogen, total Kjeldahl nitrogen, oil and grease, total phosphorous, pH, and chromium in the effluent show that the treatment system operates well. Further, no chromium was detected in the lagoon influent or effluent.

## **2. Site 2 - "B" Street Landfill**

The "B" Street landfill is located in the northwest corner of the base and served as the main base sanitary landfill between 1956 and 1969, when the existing landfill went into operation. Materials dumped at the landfill included general refuse such as garbage, concrete, rubble, fill, empty drums, and trees, and industrial wastes such as waste oils, fly ash from the heat plant, solvents, jet fuel, tank-cleaning sludge, and possibly up to 20 drums of DDT. Refuse and wastes were placed in trenches 12 to 14 feet deep and either burned or covered with fill. Currently, the site is covered by small piles of dirt fill, concrete, rubble, empty drums, and refuse. Some of the shallow trenches are still visible. The potential for environmental impact at Site 2 is based on the suspected presence of hazardous wastes in the landfill.

## **3. Site 8 - Existing Fire Department Training Area**

Site 8 is located about 1,000 feet southeast of the end of the flight line and has been used as a training site for the fire department since 1962. The site consists of two buildings and a burn area in which a steel aircraft skeleton is encircled by low earthen berms. Prior to 1975, waste fuel, oils, and lubricants were burned in the fire department exercises, but thereafter only jet fuel (JP-4) has been used. Exercises are currently conducted one to three times per month and consume 300 to 500 gallons of fuel for each fire. Although most of the fuel is probably consumed by the fire, the potential for environmental impact at this site is based on the portion of the fuel remaining in the soil.

4. Site 11 - Fuel Hydrant System Leak/Spill Area

Site 11 is located on the flight line between the No. 3 and No. 4 jet fuel hydrant stations. As much as 64,000 gallons of jet fuel were spilled in the vicinity of Site 11 in two incidents in the late 1950s. The potential for environmental impact is based on the possibility that fuel may still remain below the ground surface.

5. Site 12 - Entomology Shop Yard

Site 12 is located immediately northwest of the entomology shop, Building No. 2206. Pesticide (insecticides, herbicides, and rodenticides) application equipment has been filled and cleaned in this building since the late 1960s. Prior to about 1981, wash water was allowed to drain outside the building on the ground surface. Currently, the wash water is collected in an underground tank and analyzed before disposal. Past soil samples from this site have yielded low concentrations of several pesticides, including DDT. The potential for environmental impact is based on the presence of pesticides at the site.

E. IDENTIFICATION OF POLLUTANTS SAMPLED

Chemical analyses of ground water and soil samples included some or all of the parameters listed in Table 1. Ground water samples from the monitor wells and the base wells were analyzed for all the parameters in Table 1 plus field measurements of pH, specific conductance, and temperature. Soil samples from Site 8 were analyzed for TOX, TOC, oil and grease, total metals, and phenols. Soil samples from Site 11 were analyzed for TOX, TOC, oil and grease, and heavy metals. Soil samples from Site 12 were analyzed only for insecticides using EP toxicity extraction.

F. IDENTIFICATION OF THE FIELD TEAM

The field work required for Phase II, Stage 1 was completed by Mr. Steven Johnson, Staff Hydrologist, who supervised both the monitor well installation and soil sampling activities. Appendix F contains a description of his qualifications.

TABLE 1

PARAMETERS, LIMITS OF DETECTION FOR SOIL AND GROUND WATER ANALYSES,  
AND WATER QUALITY STANDARDS

Constituent	Limit of Detection, Soil	Limit of Detection, Water (µg/L)	Public Drinking Water Standard (µg/L)
<u>Pesticides*</u>			
Aldrin	0.01 µg/L	0.005

## **II. ENVIRONMENTAL SETTING**

### **A. GEOGRAPHIC LOCATION**

Mountain Home AFB occupies about 5,800 acres in Elmore County, Idaho on a plateau about 2 miles north of the Snake River (see Plate 1). The base is about 10 miles southwest of the city of Mountain Home and about 50 miles southeast of Boise.

The base is located on the Mountain Home Plateau, which is a rolling upland plain with occasional volcanic cones or buttes rising several tens to a few hundred feet above the plain. The elevation of the plain ranges from 2,700 feet to about 3,200 feet and is about 3,000 feet in the vicinity of the base (Mundorff et al., 1964). The surface of the plain rises 300 to 500 feet above the Snake River, which flows along the southern edge of the plateau.

The Mountain Home Plateau is drained by several intermittent streams that are tributaries of the Snake River. Canyon Creek is an intermittent stream closest to the base and receives stormwater that is occasionally discharged from a dam along the north side of the west wastewater lagoon.

The average annual precipitation at the base is about 8 inches and falls principally in the winter and spring. Mean monthly temperatures range from 30°F in January to 76°F in July. Annual average lake evaporation in the vicinity of the base is about 35 inches (CH2M Hill, 1983). Therefore, the potential of local precipitation infiltrating directly into the aquifer is small.

### **B. REGIONAL GEOLOGY AND HYDROGEOLOGY**

The Mountain Home Plateau is underlain by over 10,000 feet of volcanic and sedimentary rock, which was deposited upon the Idaho Batholith. The Idaho Batholith is composed of silicic volcanic rocks and forms a trough in which the overlying sediments and volcanic rocks were deposited. In ascending order, the formations overlying the Idaho Batholith include the Miocene Age Idavada Volcanics, consisting of about 2,000 feet of silicic volcanic rocks. Next in the sequence is the Idaho Group, ranging in age from Pleistocene to Pliocene and consisting of the Glens Ferry Formation and the Bruneau Formation. These two formations consist of basalt flows interbedded with layers of silt and sand that were deposited during interflow periods. Overlying the Idaho Group is basalt of the Snake River Group, which is Holocene and Pleistocene in age, and unconsolidated alluvial deposits, for a total thickness of about 900 feet. The basalt of the Snake River Group consists of up to 550 feet of several basalt flows, which originated from volcanic sources as much as 60 miles east of the base (Malde et al., 1963). Bedrock beneath the plateau is mantled by a thin layer of eolian sand and silt.

All of the formations underlying the Mountain Home plateau yield varying amounts of ground water. The most important aquifers are the Bruneau and Glenns Ferry Formations of the Idaho Group, which comprise a regional deep aquifer. Also present in some areas is a localized shallow aquifer comprised of alluvium in which the saturated thickness is adequate to yield a usable amount of water to wells.

Both the Bruneau and Glenns Ferry Formations contain highly permeable layers of fractured and porous basalt and coarse sand and gravel. Well yields range up to 350 gallons per minute (gpm) from the Glenns Ferry and up to 3,500 gpm from the Bruneau (Young, 1977). Depth to ground water is generally 200 to 400 feet below ground (Norton et al., 1982). Ground water quality in the regional aquifer is suitable for most purposes. Specific conductance is generally less than 500  $\mu$ mhos/cm with low hardness and low concentrations of major ions such as calcium, magnesium, potassium, sulfate, and nitrate (Parlman, 1982). Regional ground water flows toward the south and discharges into the Snake River, often in the form of springs or seeps emanating from the steep margins of the plateau. Two large springs, Halls Ferry Springs and Weatherby Springs, issue from the Bruneau Formation at points in the Snake River Canyon directly south of the base.

The main body of shallow ground water in the vicinity of the base underlies the city of Mountain Home. The perched ground water is maintained by leakage from the Mountain Home Reservoir and water distribution canals and from infiltration from Rattlesnake Creek and Canyon Creek. Depth to water is highly variable, ranging from less than 10 feet to more than 100 feet. Shallow ground water flows southward and eventually recharges the deeper, regional aquifer (Norton et al., 1982).

The principal recharge area for the aquifer underlying the Mountain Home Plateau is in the mountains north of the Plateau, where precipitation infiltrates directly into rock outcrops. Recharge from the plateau's surface is very limited because of the low annual precipitation, relatively high evaporation rate, and the deep water table. A small amount of recharge is provided by deep percolation of intermittent stream flow and excess irrigation water.

### C. GENERAL BASE HYDROGEOLOGY

The volcanic rocks and alluvial deposits in the vicinity of Mountain Home AFB generally behave as a single unconfined aquifer. However, locally confined conditions may occur due to the presence of discontinuous layers of slowly permeable materials. Ground water in the base vicinity is available mainly from the fractures, cinder zones, and interflow zones in the basalts of the Bruneau Formation, in which the depth to water ranges up to several hundred feet below ground. All of the base wells and private wells located within 2 miles of the base are completed in the

Bruneau Formation (see Tables 2 and 3). Ground water is also available from saturated gravel aquifers in stream channels and from the Glenns Ferry Formation.

Ground water levels were measured in areas near the base in 1976 (Young, 1977), 1980 (Lindholm, 1983), and 1981 (Norton et al., 1982). Depth to water ranged from 300 feet to more than 600 feet below ground or from elevation 2800 near Mountain Home to 2650 beneath the base. The water table in these years sloped toward the south, southwest, and west and showed significant cones of depression centered beneath Mountain Home, the Cinder Cone Butte area, and an area immediately east of the base. In 1981, the latter cone of depression contributed an easterly component to ground water flow causing the water table to slope to the southeast at a rate of about 30 feet per mile.

Hydrographs shown by Norton et al. (1982) show that ground water levels have been declining at 2 to 4 feet per year since 1967. The decline is due to excessive pumping and below average recharge to the aquifer. As of 1980, about 600 acre-feet per year (ac-ft/yr) was being mined from the regional aquifer beneath the Mountain Home Plateau, and currently approved ground water permits would increase the deficit to 28,100 ac-ft/yr when they are developed. In addition to excessive withdrawals, recharge decreased below normal between 1974 and 1980. Although precipitation was above normal at Mountain Home during that period, it was below normal in the mountains east of the plateau, where the regional aquifer is recharged by precipitation falling on rock outcrops. Precipitation falling on the plateau is a less important source of recharge.

The pumping rates of base wells and private wells within 2 miles of the base indicate that the regional aquifer is highly transmissive. The specific capacity of a well is the rate of discharge in gallons per minute produced by the well per foot of drawdown (gpm/ft) and is proportional to the transmissivity of the aquifer. Specific capacities of the base wells are listed in Table 2 and ranged from 50 to 257 gpm/ft. Specific capacities reported for private wells ranged from 40 to 412 gpm/ft (see Table 3). Using the method of Theis (1963) for converting specific capacity to transmissivity and a storage coefficient of 0.03 from Mundorff et al. (1964), the transmissivity ranges from 65,000 to 650,000 gallons per day per foot (gpd/ft). These values are within the range of transmissivities reported by Mundorff et al. (1964) from pumping tests in wells in other areas of the Snake River Plain aquifer. Their values ranged from a few thousand to tens of millions of gallons per day per foot.

Ground water quality in the regional aquifer is high enough for most purposes. Table 4 lists chemical analyses from the base wells that were sampled in 1980. The USEPA primary and secondary drinking water standards are also listed for comparison. With the exception of MH-3, concentrations of all the constituents meet both sets of standards.

However, ground water quality has deteriorated since the initial base wells were installed in 1948. CH2M Hill (1982) noted that concentrations of nitrate, chloride, and sulfate in the former MH-1 steadily increased between 1960 and 1974, when the well was removed from service. Base wells MH-2, MH-3, MH-4, and MH-5 have also yielded increasing concentrations of nitrate, sulfate, and chloride since about 1960. The concentrations of those constituents in MH-6 have risen only slightly since 1964. Plate 3 shows the increase of specific conductance, which is a collective measurement of the dissolved ion concentration, in base well water since 1948.

Chemical analyses for base well water reported by Parlman (1982) show that all the principal cations and anions in the analyses except iron, manganese, phosphorus, and silica have increased in concentration since 1960. There are two primary sources for the ions: deep percolation of contaminants from the ground surface and mixing of ground water from the Glenns Ferry Formation with ground water in the Bruneau Formation.

The Glenns Ferry Formation yields lower quality ground water than the Bruneau Formation because it consists of lacustrine, fluvial, and floodplain sediments (Ralston and Chapman, 1968). Soluble ionic compounds were concentrated in the sediments during deposition by evaporation and subsequently leached by ground water. In contrast, the Bruneau Formation consists primarily of resistant basalt, which contributes relatively few ions to solution. Table 5 compares the quality of water from two wells completed in the Glenns Ferry Formation with the pre-1958 ground water quality determined by the average of seven analyses of water from MH-3. The MH-3 analyses represent the ground water quality in the Bruneau Formation before it began deteriorating in about 1960 and are similar to pre-1958 analyses from other base wells. Ground water from the Glenns Ferry Formation contains significantly higher concentrations of chloride, sulfate, calcium, sodium, zinc, and other major ions than the MH-3 analyses. However, concentrations of nitrate, iron, manganese, and phosphorus are similar in the two sets of analyses.

Table 6 was prepared to show the amount of dissolved material represented by the increase in concentrations of some of the parameters in the base well analyses between about 1960 and 1980. The 1980 concentration of each parameter was estimated by averaging the concentrations in Table 4, and the MH-3 analyses in Table 5 were the source of the 1958 concentrations. Other assumptions are given in Table 6. The estimates show that several hundred tons of each constituent have been added to ground water in the Bruneau Formation to account for the increases between 1958 and 1980. Chloride concentration in the Glenns Ferry Formation is not high enough to account for the entire increase, although there could be locally higher concentrations than shown by the two analyses in Table 5. In the base vicinity, road and runway salting are likely sources of chloride. The principal feedlots (Simplot), which are also potential sources of chloride, are downgradient from the base at the base of the Snake River bluffs. Increases in sulfate, calcium, and sodium may be due to mixing with water from the Glenns Ferry Formation, although deep percolation of excess irrigation water is suggested from analyses of MH-3, which is much higher in many constituents than waters from the Glenns Ferry Formation. In general, pre-1958 concentrations of nitrate in the Bruneau Formation and current concentrations of nitrate in the Glenns Ferry Formation are similar, suggesting deep percolation of fertilizers and excess irrigation water to the Bruneau Formation.

Although no current ground water levels from the Glenns Ferry Formation are available, it is possible that the water level in the Bruneau Formation could decline below the water level in the Glenns Ferry Formation and consequently induce an upward gradient between the formations. Upward flow from the Glenns Ferry Formation into the Bruneau Formation could follow fractures or other permeable zones in the basalt. Another alternative is that upward flow only occurs as a result of drawdown when particular base wells such as MH-2, MH-3, or MH-5 are in operation. The constantly declining water levels would induce an increasing amount of upward flow from the Glenns Ferry Formation.

#### D. SITE-SPECIFIC GEOLOGY AND HYDROLOGY

This section presents the results of surface and subsurface investigations conducted during Phase II, Stage 1 at Sites 1, 2, 8, 11, and 12 at Mountain Home AFB. The field program is described in Section III, and the results of the chemical analyses are presented in Section IV. Monitor well and boring logs are presented in Appendix A.

TABLE 6

## ESTIMATED AMOUNTS OF MATERIALS ADDED TO GROUND WATER OF THE BRUNEAU FORMATION, 1958-1980

Parameter	1958 Concentration (mg/L)	1980 Concentration* (mg/L)	Increase 1958 to 1980 (mg/L)	Increase in Tons of Dissolved Material	Glenns Ferry Formation Concentration (mg/L)	Possible Sources
Chloride	3.1	60	57	600	22-28	Glenns Ferry fm., road salting, septic tanks, feedlots
Sulfate	6.5	120	114	1,100	61-85	Glenns Ferry fm., excess irrigation water
Calcium	12	70	58	570	64-68	Glenns Ferry fm., excess irrigation water
Sodium	10	27	17	170	34-35	Glenns Ferry fm., road salting, excess irrigation water
Nitrate	1.5	12	10	100	0.92-1.1	Fertilization, excess irrigation water, feedlots, septic tanks

## Assumptions:

Source of analyses: 1958, Table 5; 1980, Table 4 (average of all wells).

Aquifer area: 9 square miles

Saturated thickness: 125 feet

Porosity: 0.01

Volume of ground water represented by water analyses:  $9 \times 10^9$  liters.

\*Concentrations taken as an average of base wells MH-1, MH-3, MH-5, and MH-6 sampled in November 1980.

### 1. Site 1 - Lagoon Landfill

Site 1, known as the lagoon landfill, served as the main base landfill between 1952 and 1956, but has since been covered by the east and west wastewater lagoons (see Plate 2). One monitor well (MW-1) was installed at the midpoint of the dike between the two lagoons, which is the approximate center of the original landfill, as shown in Plate 4.

The subsurface profile at Site 1 consists of 24 feet of brown silty fine to coarse sand underlain by black vesicular basalt with fine-grained crystals of olivine and plagioclase, which was present to the completion depth of 402 feet. The basalt weathers to dark reddish brown and contains occasional layers of cinders or broken interflow zones. The depth to ground water was about 333 feet below ground.

### 2. Site 2 - "B" Street Landfill

Site 2 is the "B" Street landfill and served as the main base sanitary landfill between 1956 and 1969. One monitor well (MW-2) was installed near the southwest side of Site 2 (Plate 5), where, based on the regional gradient, it would be approximately downgradient from the former landfill. Water level measurements taken in April of 1984 indicate that local pumpage may have locally reversed the gradient. A survey of well elevations and depth to water will be required to accurately determine the direction of ground water flow.

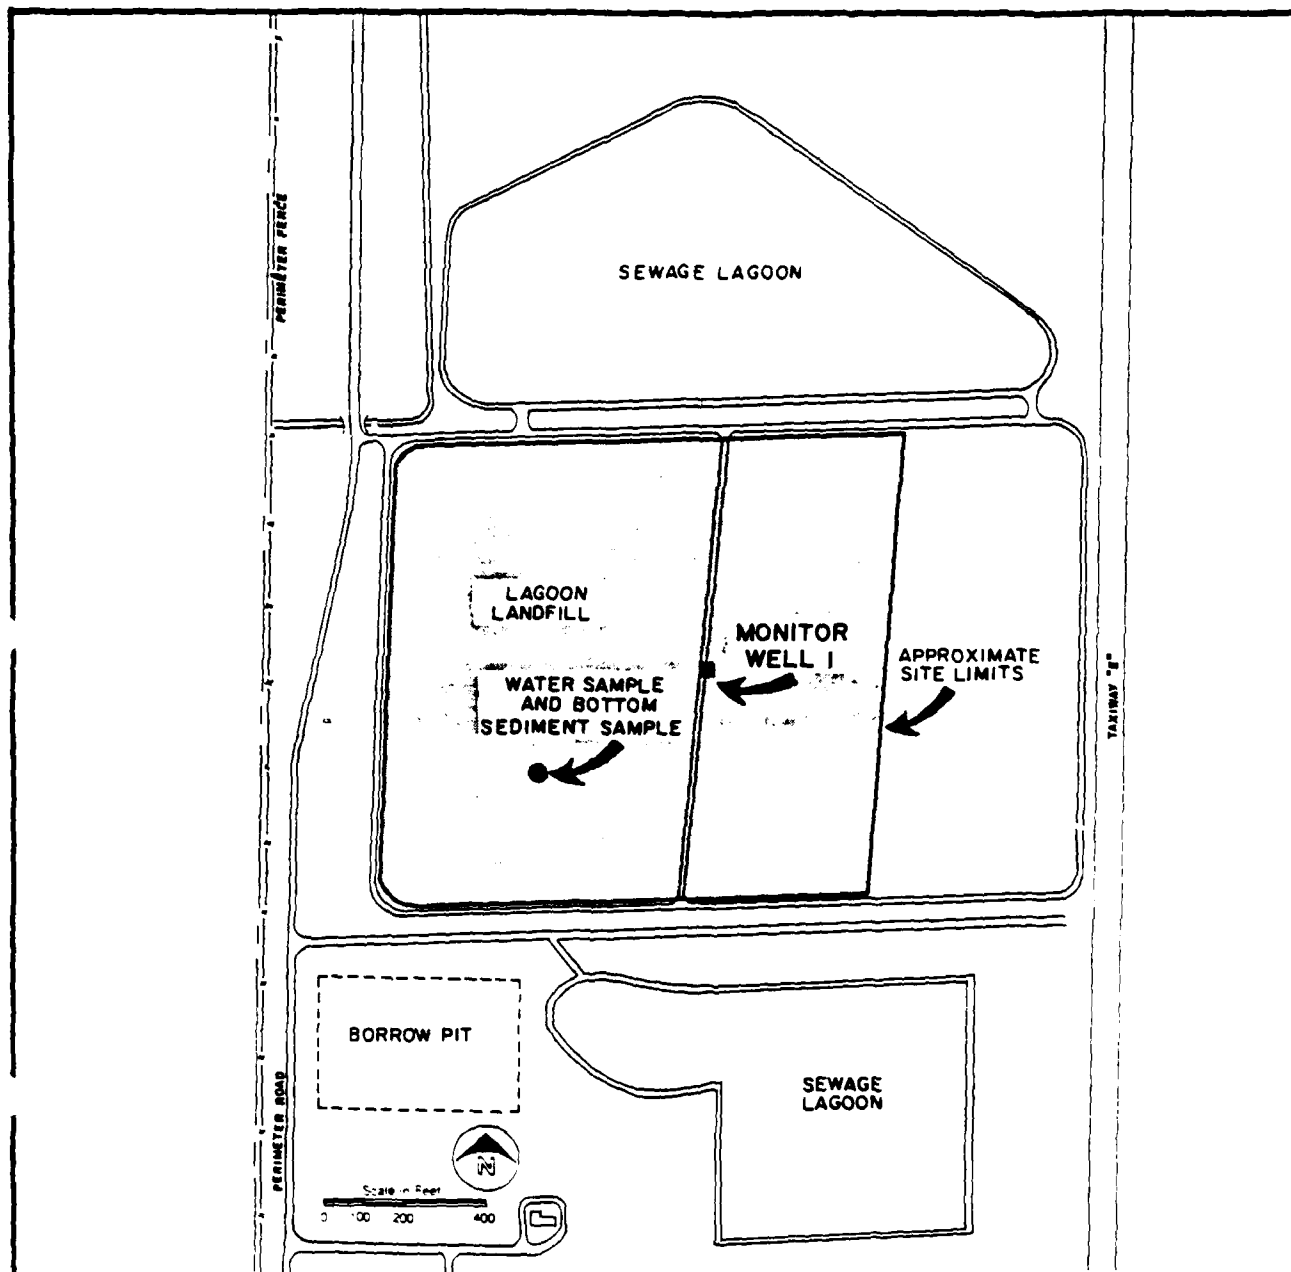

The subsurface profile beneath Site 2 consists of 18 feet of brown sandy silt with basalt fragments and caliche underlain by black vesicular basalt with fine-grained crystals of olivine and plagioclase, which extended to the completion depth of 410 feet. The basalt weathers dark reddish brown and contains occasional layers of cinders or broken interflow zones. The depth to ground water was about 354 feet below ground.

### 3. Site 8 - Existing Fire Department Training Area

Site 8 is the current fire department training area. Three borings were drilled at the site. Borings DM-4 and DM-5 were drilled outside the bermed area, and Boring DM-6 was drilled inside the bermed area (Plate 6).

The ground surface at Site 8 consists of brown fine to coarse sand and gravel, which extends to a depth of about 6 inches. Gray silt with some fine sand and occasional caliche and gravel extended from the surficial unit to about 4 feet below ground. Brown silty, slightly to moderately calichefied, fine sand with occasional coarse sand or gravel was found between about 4 and 7 feet below ground. All three borings were terminated at 10.5 feet in brown fine to medium sand.

FILE 115-186 BY            DATE            CHECKED BY            DATE           

The moisture content of the analyzed soil samples ranged from 2.2 percent to 15 percent. The concentrations of organic vapors measured by the HNU (photo-ionization detector) ranged from less than 1 to 195 ppm in all the borings. Hydrocarbon and septic-like odors were detected to a depth of about 8 feet below ground in all the borings. Odors were very strong inside the bermed area at Boring DM-6 but less noticeable at DM-4 and DM-5.

#### **4. Site 11 - Fuel Hydrant System Leak/Spill Area**

Several thousands of gallons of jet fuel were spilled in the 1950s at Site 11. Three borings (DM-1, DM-2, and DM-3) were drilled at the site along a line extending southwest from the flight line, midway between fuel hydrants 3 and 4 (Plate 7). Boring DM-1 is about 100 feet from the edge of the taxiway, and Borings DM-2 and DM-3 are at 50-foot intervals from DM-1.

The ground surface at Site 11 consists of sparse grass and brown fine sandy silt. The silt extended to the termination depth of 10.5 feet in DM-2 and to 9.6 feet in DM-3 except for a 1.5-foot sand layer at 7 feet below ground in DM-3. Basalt was encountered at 2.6 feet in DM-1, although it is unknown whether it was a large boulder or bedrock.

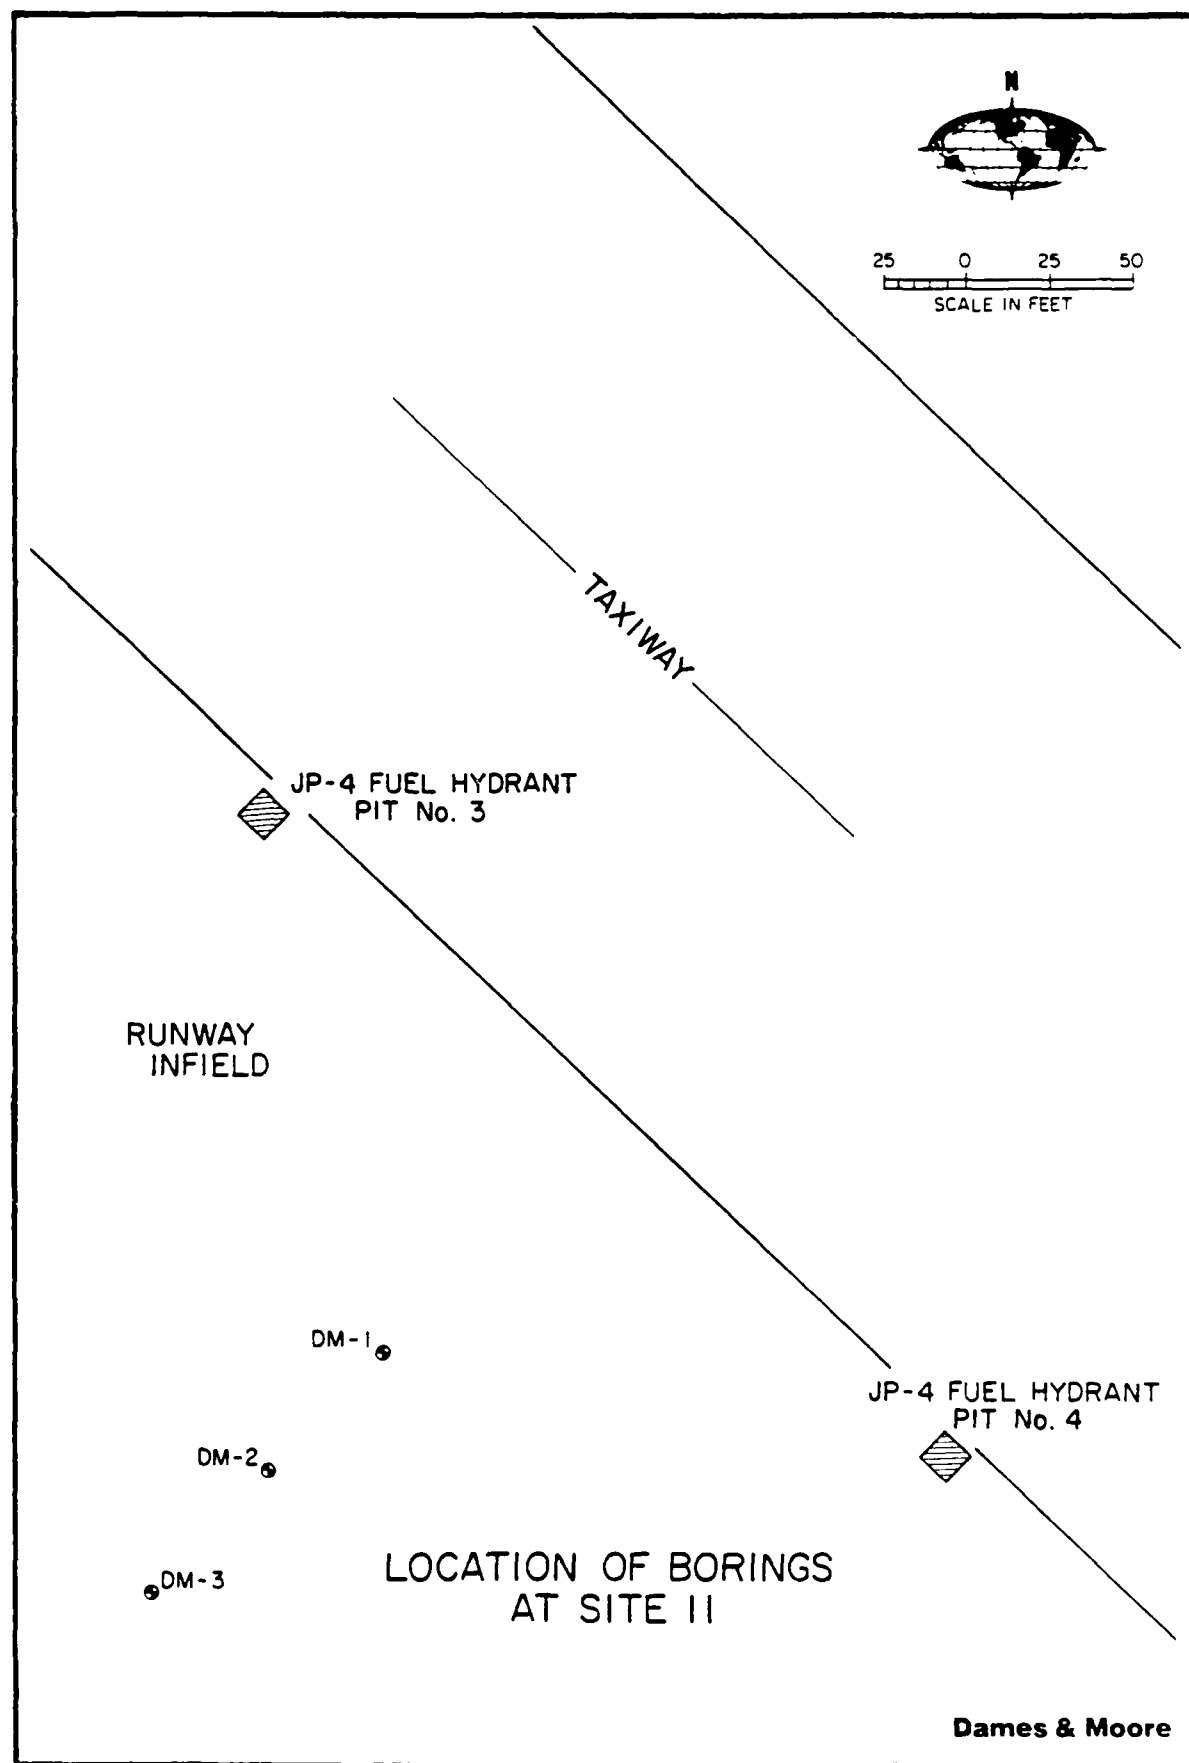

HNU readings from the borehole ranged from less than 1 to about 20 ppm, although no odors were detected. The moisture content of the soil samples ranged from 2.2 to 15 percent.

#### **5. Site 12 - Entomology Shop Yard**

Site 12 is the driveway area adjacent to the northwest side of the entomology shop (Building 2206). Borings DM-7, DM-8, and DM-9 were drilled at 10-foot intervals in a line perpendicular to the building (Plate 8).

The soil at Site 12 consisted of brown, fine sandy silt with trace clay and gravel to a depth of 2.5 to 5 feet below ground, underlain by brown, silty fine sand to the completion depth of all the borings (6.5 feet). A single HNU reading of 80 ppm was noted at a depth of about 1 foot in DM-9. All the other readings were 5 or less, and no unusual odors were detected. Moisture contents ranged from 4.6 to 14 percent.

## **E. HISTORIC GROUND WATER PROBLEMS**

Ground water in the vicinity of Mountain Home AFB provides water for domestic use and irrigation. However, steadily declining water levels may decrease the availability of ground water in the future.

As discussed previously, ground water is currently mined at a rate of about 600 ac-ft/yr, and the overdraft would increase to 28,108 ac-ft/yr when all the outstanding ground water permits for irrigation are developed. If all the ground water applications currently pending are developed, the overdraft would be about 48,000 ac-ft/yr (Norton et al., 1982).

The overdrafts have caused constantly declining ground water levels in the vicinity of the base. Water level records are available from one well immediately northwest of the base (4S-5E-19CBA1) and two wells located about a mile east of the base (4S-5E-25BBC1 and 4S-5E-24AAB1) (Young, 1977; Norton et al., 1982). Water levels in all three wells have declined between 2 and 4 feet per year since 1967. Since 1976, ground water levels have declined as much as 45 feet in an area immediately east of the base (Norton et al., 1982).

Both state and federal agencies have responded to the declining water levels in the Snake River Basin. On May 7, 1981, the Idaho Department of Water Resources designated a 128-square-mile area about 6 miles north of the base as the Cinder Cone Butte critical ground water area (CGWA). Ground water levels in that area declined as much as 35 feet between 1976 and 1981 (Norton et al., 1982).

## **F. LOCATIONS OF WELLS ON AND OFF BASE**

Drilling logs and well construction information were collected for the base production wells and for private wells located within 2 miles of the base. Plate 2 shows the locations of the base wells and private wells, and they are summarized in Tables 2 and 3, respectively. The sources of the well information included logs filed with the Idaho Department of Water Resources, Young (1977), Norton et al. (1982), and Parlman (1982).

The private well inventory consisted of 35 wells located within a radius of 2 miles of the base. The wells ranged in depth from about 400 to 735 feet and are used for either domestic or irrigation water supplies. Generally a 6-to 20-inch diameter borehole was drilled and up to about 25 feet of surface casing was installed. Most of the wells were completed as open holes below the surface casing, and only the largest production wells were cased or screened to the bottom of the borehole. The water level at installation ranged from 300 to 400 feet below ground. Pumping test results were available for only four wells, which yielded specific

capacities of 24 to and 412 gpm/ft. The wells were completed primarily in black or red basalt, presumably from the Bruneau Formation.

There are currently seven base wells in operation, and MH-8 was under construction. The wells range in depth between 400 and 610 feet and were installed periodically since 1943. The borehole for the wells ranged from 8 to 24 inches, and the entire length of the borehole was cased. A portion of the casing was perforated either at the factory or in the field with a torch. Water levels at installation ranged from about 309 to 331 feet below ground. Current water levels are listed in Table 7 and range from 320 to 368 feet below ground.

TABLE 7

WATER QUALITY PARAMETERS MEASURED IN THE FIELD

Well	Sampling Date	pH	Specific Conductivity ( $\mu$ mhos/cm)	Temperature ( $^{\circ}$ C)	Casing Volumes Pumped	Depth to Water (feet)
MW-1	11 Apr 84	7.95	1300	14	6	332.9
MW-2	11 Apr 84	8.48	210	18	5.5	353.6

West Lagoon	11 Apr 84	9.46	500	10	-	-

### **III. FIELD PROGRAM**

#### **A. DEVELOPMENT**

The field program was developed based on previous phases of the IRP. During Phase I, the sites at which hazardous materials were handled were identified, and the sites with the highest potential environmental impact were selected. A field program to confirm the site selections was then developed in Phase I and evaluated during the Phase II Presurvey.

The Phase II, Stage 1 program consisted of the following activities:

1. Installation and sampling of a monitor well at Site 1, the lagoon landfill, and one at Site 2, the "B" Street landfill.
2. Sampling of base supply wells MH-1, MH-3, MH-4, MH-5, MH-6, and MH-7.
3. Drilling, geologically logging, and sampling three borings at Site 8, three borings at Site 11, and three borings at Site 12 to depths of between 2.7 and 10.5 feet.
4. Sampling the east and west wastewater lagoons.

#### **B. IMPLEMENTATION**

##### **1. Monitor Well Installation**

The monitor wells were drilled by Elsing Drilling, Inc. from Twin Falls, Idaho using air-rotary techniques. Initially, a 12-inch boring was drilled to 49 feet, and 50 feet of 8-5/8-inch steel surface casing was cemented into the borehole. An 8-inch borehole was then drilled to the completion depth. Cutting samples were collected at 5-foot intervals and logged in the field by an experienced Dames & Moore geohydrologist. Air exhausted from the borehole was monitored for organic and explosive vapors using an HNU photoionization detector and an explosimeter. At Site 1, cuttings from MW-1 were collected in 55-gallon drums or loaded onto the back of a truck and placed in a plastic-lined trench near MW-2 at Site 2. Cuttings from MW-2 were discharged directly into a plastic-lined pit, and both piles of cuttings were covered with a plastic sheet following completion of the drilling. The cuttings did not appear to contain hazardous constituents based on visual inspection and low-level readings on the photoionization detector.

The well casing consisted of 4-inch diameter Schedule 80 PVC pipe and well screen with 0.040-inch machine-cut slots. Construction details are listed in Table 8. The casing and screen sections were connected with threaded joints to avoid using PVC solvent. Pea gravel was placed with a tremie pipe within the annulus of the borehole up to about 10 feet above the top of the screen. About 9 feet of sand with grain sizes falling between sieve sizes #8 and #120 and about 2 feet of bentonite pellets were placed on top of the pea gravel to prevent grout from invading the gravel pack. The remaining annular space was filled with a cement grout (MW-2) or two intervals of grout separated by an interval of pea gravel (MW-1). The monitor well installations were completed with a concrete pad, PVC slip-cap on the well casings, and a steel lockable cap on the surface casing. MW-1 was completed at ground surface to allow for vehicular traffic on the dike.

The wells were developed by air-lift pumping until the discharge was clear of sand. MW-1 yielded about 60 gallons per minute (gpm), and MW-2 yielded about 15 gpm. These yields were measured by directing the discharge to a location where the flow was measured with a bucket and timer. The discharge from both wells cleared up after less than an hour of pumping.

## **2. Monitor Well Sampling**

Prior to sampling, at least three casing volumes of water were bailed from each monitor well using a PVC bailer. The PVC bailer was double rinsed with distilled water prior to bailing each well. The sample jars were filled using a Teflon bailer after the specific conductance and pH of bailed water had stabilized. The Teflon bailer was double rinsed with distilled water and was then single rinsed with well water prior to bailing the samples. The samples were placed in an insulated cooler with ice and delivered to the analytical laboratory, UBTL Inc. in Salt Lake City, within 24 hours of sampling. Table 9 lists the parameters and preservatives.

Measurements of the depth to water, pH, specific conductance, and temperature were taken in the field and are listed in Table 7. The depth to water was measured with an electric tape. Measurements of pH and temperature were made with a Hach Model 19000 temperature-compensated digital pH meter equipped with a combination electrode. The meter was calibrated using pH 7 and 10 buffers. Specific conductance measurements were made with a Markson Science Model 10-B temperature-compensated conductivity meter and are reported at 25°C. The portion of the sample to be analyzed for metals was filtered through a 0.45-micron membrane in the field with a barrel-shaped pressure filter.

TABLE 8

MONITOR WELL CONSTRUCTION DETAILS

Item	MW-1	MW-2
Depth of borehole (feet below ground)	402	410
Screened interval	321 to 381*	344 to 404
Gravel pack	310 to 401	316 to 410
Fine sand seal	301 to 310	304 to 316
Bentonite seal	299 to 301	302 to 304
Cement grout	252 to 299 0 to 173	0 to 302
Gravel and sand fill	173 to 252	None
North state plane coordinate (estimated)	503,700	509,800
East state plane coordinate (estimated)	462,400	442,300
Ground surface elevation (estimated)	2990	3010
Depth to water (11 Apr 84)	332.9	353.6

\*Non-slotted PVC pipe was installed from 381 to 401 feet in order to locate the screened interval across the water table.

### 3. Base Well Sampling

Base wells MH-1, MH-3, MH-4, MH-5, MH-6, and MH-7 were sampled during Phase II, Stage 1. Prior to sampling, the depth to water was measured, where possible, with the built-in air line and direct reading gauge. The pump was then started and samples were collected after at least three casing volumes had been discharged from the well. The sample bottles were filled from a spigot on the discharge line. Measurements of pH, specific conductance, and temperature are listed in Table 7. The sample bottles were placed in an insulated cooler with ice and delivered by air freight to UBTL within 24 hours of sampling. MH-7 was sampled in place of MH-2, which was inoperative.

### 4. Wastewater Lagoon Sampling

Grab samples from the east and west wastewater lagoons were collected in a large plastic container and then poured into the individual sample bottles. The sample bottles were placed in an insulated cooler with ice and delivered by air freight to UBTL within 24 hours of sampling. Measurements of pH, specific conductance, and temperature were made in the field as described above and are listed in Table 7.

### 5. Collection of Soil Samples

Soil borings were drilled by Erickson-Ford Company of Boise, Idaho, using hollow-stem auger techniques. The borings were drilled to the sampling depth using the augers, and the sample was collected using the Dames & Moore Type "U" split-barrel sampler. The sampler was driven 18 inches or to refusal with a 140-pound hammer, and the soil sample was retained in 2.5-inch diameter by 1-inch brass rings. A portion of the soil retained in each of the brass rings was scraped into the sample jar. The brass rings were cleaned with detergent, water, and acetone between samples, and the sampler parts and hollow-stem augers were cleaned with soap and hot water between borings. The soil samples were placed in an insulated cooler with ice and delivered to UBTL within 72 hours after sampling. The boreholes were backfilled with powdered bentonite to within a foot of the ground surface. The remainder of the boreholes was filled with concrete along with a small round steel marker attached to a 3-foot piece of rebar. Organic or explosive vapors emanating from the boreholes were measured at each sampling interval with an HNU photoionization detector and an explosimeter. The measurements are listed on the boring logs in Appendix A. The soil samples that yielded the highest readings were subsequently submitted for analysis in quantities prescribed by the scope of work.

#### IV. DISCUSSION OF RESULTS AND SIGNIFICANCE OF FINDINGS

##### A. DISCUSSION OF RESULTS

This section presents a discussion of the chemical analyses of ground water and soil samples collected during field investigations at the sites shown in Plate 2. The second part of this section discusses the significance of the results.

The standards with which the results of the chemical analyses are compared are the primary drinking water standards.

##### 1. Site 1 - Lagoon Landfill

The field investigation at Site 1 consisted of installing and sampling a monitor well and sampling the east and west lagoons. The field investigation is described in Section 3.0, and the complete analyses are presented in Appendices B and D.

The parameters detected in the monitor well (MW-1) sample included lead, cadmium, TOX, and TOC. The lead concentration met, but the cadmium concentrations exceeded the primary drinking water standards. Although there are no standards for TOX and TOC, the concentrations of those parameters were low (see Table 10). Despite the low concentration of TOX, it is higher than background suggested by the levels in the base wells, and it indicates that some halogenated wastes may be present in the ground water. Because none of the pesticides were detected in MW-1, the organic halogens may include chlorinated solvents, which have been used at the base.

Heptachlor, delta-BHC, and silver were detected in the east lagoon sample, and TOX, TOC, and oil and grease were detected in both the lagoon samples. Standards exist only for silver, and the concentration found in the east lagoon is below that standard. The TOX concentrations in the lagoons were elevated well above the background levels suggested by the base wells.

##### 2. Site 2 - "B" Street Landfill

The field investigation at Site 2 consisted of installing and sampling the monitor well (MW-2). The field investigation is described in Section 3.0, and the complete analyses are presented in Appendices B and D.

The only detectable parameter in the MW-2 sample was TOX, which is present at a level that is equivalent to the background levels found in base water wells (see Table 10).

TABLE 10

SUMMARY OF CONSTITUENTS ABOVE DETECTION LIMITS IN GROUND WATER AND LAGOON WATER ANALYSES

Constituent	Monitor Well		Base Well				West		East	
	MW-1	MW-2	MH-1	MH-3	MH-4	MH-5	MH-6	MH-7	Lagoon	Lagoon
<u>Pesticides (µg/L)</u>										
Heptachlor	ND	ND	NA	NA	NA	NA	NA	NA	ND	0.007
delta-BHC	ND	ND	NA	NA	NA	NA	NA	NA	ND	0.08
<u>Metals (µg/L)</u>										
Lead	10	ND	NA	NA	NA	NA	NA	NA	ND	ND
Cadmium	20	ND	NA	NA	NA	NA	NA	NA	ND	ND
Silver	ND	ND	NA	NA	NA	NA	NA	NA	ND	10
<u>Others (mg/L)</u>										
TOX	0.12	0.055	0.082	0.12	0.065	0.086	0.059	0.062	1.5	1.9
TOC	4.0	ND	2.0	6.0	ND	2.0	ND	ND	20.	53.
Oil & Grease	ND	ND	0.5	ND	ND	ND	ND	ND	1.6	7.4
Phenol	ND	ND	NA	NA	NA	NA	NA	NA	ND	ND

## Notes:

- (1) Those constituents not listed above were present at concentrations less than detection limits.
- (2) Table 1 lists all the constituents analyzed, detection limits, and water quality criteria.
- (3) ND = None detected; NA = Not analyzed

### 3. Results of Base Well Sampling

Ground water samples were collected and analyzed from six base wells: MH-1, MH-3, MH-4, MH-5, MH-6, and MH-7. The base wells are located throughout the base, as shown in Plate 2. Sampling methods are given in Section III, and the complete analyses are listed in Appendix D.

Base well samples were analyzed for TOX, TOC, and oil and grease. TOX was detected in all six base well samples, TOC in three samples, and oil and grease in one base well sample (see Table 10). No water quality criteria have been established for these parameters, although all were present at low concentrations. The TOX concentrations ranged from 0.059 to 0.12 mg/L, with well MH-3 being the highest of the six wells. In the other five wells, TOX ranged from 0.059 to 0.086 mg/L.

### 4. Reliability of the Ground Water and Surface Water Analyses

The ground water quality analyses are considered to be reliable by virtue of the well construction and sampling measures taken in the field to insure that the samples were representative; by virtue of quality control procedures in the laboratory; and because of the monitor well locations.

The monitor wells were screened above and below the water table where low density organic contaminants would be concentrated. After the monitor wells were installed, they were thoroughly developed by air-lift pumping to remove all effects of drilling and installation and to improve the flow of ground water into the wells. Pumping was continued until the specific conductance of the well water stabilized and the discharge was clear of sediment. At least three casing volumes of water were removed from the monitor wells and the base wells prior to sampling to insure that the samples were representative of ground water in the formation. The monitor well samples were collected with a Teflon bailer to minimize agitation and consequent aeration of the sample, which could volatilize organic chemicals. The Teflon bailer does not absorb any chemicals from the sample and, therefore, prevents any adverse affects of sample chemistry and cross-contamination of subsequent samples.

The monitor wells were installed at locations where they would most likely intercept contaminants from the two waste sites. MW-1 was installed in a dike between the east and west lagoons, which coincides with the approximate center of the former landfill. Based on available site hydrogeologic data, MW-2 was installed at a location thought to be downgradient from the "B" Street landfill. However, it is possible that the ground water gradient may have been altered due to pumping of base wells.

The laboratory quality control (QC) program is described in detail in Appendix B. In general, analyses of duplicate and spiked samples were satisfactory. Analyses of method blanks were also acceptable.

## 5. Background Concentrations

No historic background concentrations of organic parameters or pesticides are available for ground water beneath Mountain Home AFB, but some information exists for concentrations of inorganic constituents. Ground water used at the base is obtained from the Bruneau Formation. As discussed in Section II.C, ground water quality in that formation has deteriorated somewhat since about 1960. The ground water quality prior to 1960 is approximated by the concentrations listed in Table 5, which are based on analyses of MH-3 samples prior to 1958. Current background conditions are shown by the analyses in Table 4, which are based on samples from MH-1, MH-3, MH-5, and MH-6 obtained in 1980. Despite the deterioration, concentrations of all the constituents from all the wells, except MH-3, meet the primary and secondary drinking water standards. Concentrations of nitrate-nitrogen and total dissolved solids in MH-3 samples exceed the primary and secondary drinking water standards.

No historic analyses of the organic content of ground water beneath the base were available, and the absence of any water quality criteria for TOX and TOC precludes any regulatory basis for comparing the concentrations obtained from water and soil samples. However, the following information provides some basis for interpreting the quality of water and soil indicated by TOX and TOC measurements.

TOC is a measure of the organic carbon in a sample, regardless of whether the source is natural or man-made. Organic carbon in uncontaminated ground water is derived from humic and fulvic acids dissolved from sediments, dissolution of carbonates containing organic carbon, and other dissolved organic materials. Background concentrations are typically less than 10 mg/L, especially in an aquifer such as the Snake River Plain aquifer, in which ground water would be relatively aerated and oxidizing conditions probably prevail. In an aquifer in which there is little ground water movement, organic-rich aquifer material, and relatively anaerobic or reducing conditions, TOC concentrations could be expected to range up to 100 mg/L. Industrial wastes may contain as much as 200,000 mg/L, and consequently, highly contaminated ground water may yield any concentration including several thousand milligrams per liter of TOC.

All soils contain varying fractions of organic materials that, in turn, contain different concentrations of organic carbon. The organic carbon analyses for the Mountain Home samples were performed on soil slurried with water and analyzed using the TOC methodology (USEPA Method 415.1) for water. No TOC methodology for solid samples has been approved by USEPA to date. The Mountain Home soil analyses will be evaluated only on a relative basis, especially because no background samples were specified by the Phase II, Stage 1 scope of work.

TOX is a measure of organic halogens containing chlorine, bromine, and iodine that can be adsorbed by activated carbon. The same methodology (USEPA Method 9020) was used for both soil and water analyses. A water extract was taken from the soil samples according to USEPA methods (USEPA, 1982). Chlorinated and brominated organic chemicals are not naturally produced, but are manufactured chemicals such as pesticides, PCBs, PBBs, and solvents. Therefore, virtually any concentration of TOX is an indication of organic contamination.

## **B. SIGNIFICANCE OF FINDINGS**

Based on the results described in the previous section, this section will estimate, to the degree possible, the extent of contamination at each site and the risk to human health, if any, that the contamination poses.

### **1. Extent of Contamination at Site 1 - Lagoon Landfill**

The ground water analyses from Site 1 show evidence of organic contamination. The concentration of TOC is probably at background levels, but the TOX concentration, approximately 50 percent higher than background from base wells, indicates that some contamination has occurred. Although the cadmium concentration in the MW-1 sample exceeded the primary drinking water standard, it is unlikely that it represents contamination by base activities. The insignificant concentrations of lead, chromium, and other inorganic constituents, which may indicate inorganic contamination, suggests that the cadmium is from a natural source or is a laboratory error. Unfortunately, no other cadmium analyses could be located from area wells for comparison. Resampling and analysis for cadmium is warranted. The extent of ground water contamination beneath Site 1 cannot be estimated from one well.

The presence of elevated heptachlor, delta-BHC, TOX, and TOC in the lagoon samples indicates that organic contaminants are present in the lagoons. The oil and grease in the lagoon samples may account for most of the TOC, and the detected pesticides and solvents may be the source of the TOX. Because of the high TOX concentrations and the presence of two pesticides, the lagoons may be the source of the contaminants that are responsible for the organic halogens detected in the MW-1 sample.

## 2. Extent of Contamination at Site 2 - "B" Street Landfill

TOX was detected in concentrations equal to the background levels found in the base supply wells. However, it is not known whether MW-2 was actually installed downgradient of the landfill, since localized changes in the water table may have occurred due to base well pumping.

## 3. Extent of Contamination Indicated by Base Well Samples

The TOX concentrations in the base well (and monitor well) samples indicate that some halogenated organic compounds are present in ground water beneath the entire base. The concentrations ranged from 0.059 to 0.086 mg/L in all the base well samples except MH-3, which contained 0.12 mg/L. In contrast, the TOC concentrations are too low to indicate conclusively the presence of contaminants. The magnitude of the contamination is difficult to evaluate because many different organic compounds contribute to TOX, and each compound has its own degree of health risk.

The highest TOX concentrations were in the MH-3 and monitor well samples. MH-3 has a history of deteriorating water quality (see Section II.C) due to additions of inorganic salts infiltrating downward from surface sources or migrating upward from the Glenns Ferry Formation. The presence of organic contaminants in the MH-3 sample indicates that there may be a pathway for contaminants to travel from the ground surface to the water table. The existence of a pathway is also suggested by the relatively high TOX concentrations in the monitor well samples. Contaminants may be infiltrating from the "B" Street landfill, lagoons, the former lagoon landfill, road salting, or irrigation.

The Phase II, Stage 1 results suggest that base waste disposal areas are the source of the organic contaminants, although there may also be off-base sources. The sample from MH-6, which is approximately upgradient of all the waste disposal areas, contained 0.059 mg/L of TOX, slightly less than the downgradient sample from MH-5 (0.086 mg/L). The MH-6 sample also contained the lowest concentration of TOX of all the samples. These observations suggest that organic contaminants are being added to ground water as it passes beneath the base. However, the halogenated compounds in the MH-6 sample may have originated from pesticides, herbicides, solvents, or other organic chemicals used north of the base, although until local ground water flow directions beneath the base are better known, it is conceivable that contaminants from the "B" Street landfill could be intercepted by MH-6. The regional ground water flow direction is south, but local variations would be created when the base wells are in operation. Identification of the individual organic compounds will also help to determine whether base or off-base sources are responsible for the observed contamination.

#### 4. Extent of Contamination at Site 8 - Existing Fire Department Training Area

Site 8 is the existing fire department training area where jet fuel is currently burned for fire training exercises. The results of the soil analyses are listed in Table 11.

Phenol and lead concentrations were relatively uniform, but there was wide variation among the concentrations of TOX, TOC, and oil and grease. The variation is due to the unpredictable mixture of the combustion products of waste fuel, oils, lubricants, and jet fuel that has accumulated. However, the concentrations of all three parameters generally decrease with depth. Oil and grease and TOC appear to be at background levels at about 7.5 feet. The background value for TOX is unknown, but a comparison of the TOX concentrations from Site 11 and Site 8 soil samples indicate that the maximum background concentration is probably about 250 micrograms per liter ( $\mu\text{g/L}$ ). On this basis, the TOX measurements at 7.5 to 9 feet in DM-5 do not indicate any contamination, although contamination may be present at 9 to 10.5 feet in Boring DM-6. Boring DM-6 was drilled within the bermed area in which jet fuel pools before it is burned during fire training exercises and, consequently, yielded the highest degree of contamination compared with samples from the other two borings.

The extent of contamination appears to be concentrated in the upper 7.5 feet of soil, except beneath the bermed area, where it extends more than 10.5 feet below the ground surface. It is not possible at this time to estimate how much deeper the contamination may extend beneath the bermed area.

The threat to human health posed by contaminants at Site 8 is low under normal conditions. These contaminants enter the human body principally through inhalation, either as vapor or as particulate matter in aerosols. Under dust-free conditions and short-term exposures to the site, the degree of hazard is diminished by the volatility of the contaminants. Dispersion of the contaminants in the atmosphere would maintain a low degree of hazard. When exposure times amount to several hours or direct contact with site materials is necessary, the degree of hazard rises proportionately, and the threat to human health can only be evaluated by direct measurements of organic and explosive vapors. The degree of hazard would also be much greater under dusty conditions for any exposure time.

(2) ND = none detected; NA = not analyzed

5. Extent of Contamination at Site 11 - Fuel Hydrant System Leak/Spill Area

Two jet fuel spills occurred at Site 11 in the late 1950s. Table 11 lists the contaminants that were detected in the soil samples from Site 11.

TOX concentrations ranged up to 660 µg/L, and TOC concentrations ranged up to 5.6 milligrams per gram (mg/g) in soil samples from Site 11. Lead concentrations were relatively uniform, ranging from 25 to 41 micrograms per gram (µg/g). Oil and grease was detected in only two samples and in insignificant concentrations. Concentrations of all three parameters generally decreased with depth. Shallow soil samples probably contain trace amounts of organic contaminants remaining from the jet fuel spills, although the low concentrations represent little or no significant contamination.

The threat to human health posed by contaminants at Site 11 is insignificant. Under normal conditions, the site is isolated by the flight line and apron, so there is little reason for any exposure to the site. However, under dusty conditions or when direct contact with site materials is necessary, the degree of hazard will rise slightly.

6. Extent of Contamination at Site 12 - Entomology Shop Yard

Site 12 is the entomology shop yard where pesticides and rinse water containing pesticides were drained. Analyses of soil samples obtained at Site 12 are listed in Table 11.

Of the 16 pesticides in the analyses, seven were detected in EP toxicity test extractions of one or more soil samples from Site 12. The detected pesticides included p,p'-DDT, DDD, dieldrin, endrin, heptachlor epoxide, lindane, and chlordane. The concentrations range up to 2.4 µg/L of p,p'-DDT, although most of the concentrations were less than 0.1 µg/L. Dieldrin was detected in all six samples, while DDD was detected in five of the six samples, and the remaining five pesticides were detected in one or two samples each. The concentrations for endrin and lindane were far below the RCRA standard for EP toxicity (40 CFR 261.24).

The extent of contamination extends at least 1 foot below ground surface and includes the area in the vicinity of the borings, the furthest of which is located 30 feet northwest of the entomology shop (Building No. 2206). It is unknown how deep the pesticides may be present because only the upper 1 foot of soil was analyzed.

The threat to human health posed by pesticides at Site 12 is very low under normal conditions. The pesticides could be expected to enter the human body

principally through inhalation or as particulate matter attached to aerosols. Under dust-free conditions, the degree of hazard is diminished because the pesticides are typically strongly absorbed by soil particles. Under dusty conditions or when direct contact with the shop yard soil is necessary, the degree of hazard rises proportionately, and protection such as particulate filters or gloves may be advised.

## V. ALTERNATIVE MEASURES AND CONCLUSIONS

### A. ALTERNATIVE MEASURES

This section describes several alternatives for further investigating the existence of ground water contamination at Mountain Home AFB. The alternatives include annual sampling of the base wells and monitor wells, additional soil sampling at Sites 8 and 12, and other ground water investigation techniques.

The results of Phase II, Stage 1, along with existing information, revealed evidence of organic ground water contamination. However, neither the magnitude of the contamination nor the sources of the contaminants can be properly evaluated without knowing the individual organic compounds that contributed to the observed TOX concentrations. All the operating base wells and monitor wells could be resampled and analyzed for the organic parameters in USEPA Methods 601, 602, and 608. These parameters include the halogenated compounds for which there are USEPA-validated analytical methodologies. The samples could also be analyzed for all the major cations and anions to accurately assess the ground water quality beneath the base. Tracing the changes in composition of ground water from different areas beneath the base would show the effects of mixing of various waters, and would indicate the impacts of the various base facilities and disposal areas on ground water quality. One or more of the anions such as chloride or sulfate may serve as an accurate contamination indicator. The cations, along with the anions, generally define a "fingerprint" of a particular ground water type that can be recognized among different samples. Comparison of the ground water analyses can also show the occurrence of mixing of ground water from the Bruneau and Glens Ferry Formations or the addition of contaminants to the ground water system from the lagoons.

The sources of the observed organic contamination are difficult to identify without detailed knowledge of the ground water surface beneath the base. Although the regional gradient is south, local variations, which would affect the directions of contaminant migration, are created when the base wells are in operation. When the base wells and monitor wells are resampled, ground water levels could be measured and carefully converted to elevations. To accomplish this, the monitor well and base well elevations would have to be surveyed, and the depths to water in the base wells would have to be accurately converted to elevations. Installation of monitor wells to determined background conditions should be deferred until after confirmation of Phase II, Stage 1 results and definition of local gradients based on surveyed water levels.

Soil samples from Site 8 contained the highest concentrations of contaminants of all three sites. Samples from Boring DM-6, which was drilled within the bermed area, yielded contaminants at depths of 9 to 10.5 feet. Two additional borings could be drilled within the bermed area at Site 8 to define the vertical extent of contamination. Soil samples could be collected at 2-foot intervals until there is no visual or olfactory evidence of contamination. The presence of contaminants could also be detected using a photoionization detector, and the boring could be continued until the sample yields background readings. Two samples from each hole, the deepest sample in which contamination is suspected and the sample in which no contamination was detected, would be submitted for analysis of volatile and semi-volatile organics, oil and grease, and moisture content. In order to better evaluate these analyses, a third boring could be drilled in a nearby area in which no fire training has ever been conducted. This boring would be drilled to the depth at which no contamination was detected beneath the bermed area, and four samples would be submitted for analyses of the same parameters as the samples from the fire training area. Results of the soil analyses would be used to define the vertical extent and magnitude of soil contamination at Site 8.

Soil samples from Site 12 yielded evidence of low-level pesticide contamination, which could pose a potential health hazard under dusty conditions because of the vehicular traffic and human activities in the vicinity of Building 2206. Although four soil samples each were collected from Borings DM-7, DM-8, and DM-9, only the two samples from 0 to 1 foot were analyzed for pesticides. In order to determine the vertical and areal extent of the pesticide contamination, additional borings located adjacent to Building 2206 could be drilled and sampled.

Borehole geophysical methods such as resistivity, self potential, density, and gamma radiation are often used to characterize geologic and hydrologic conditions. However, they would not yield significantly more subsurface information than that collected during the drilling and sampling carried out for Phase II. Like surficial geophysical methods, borehole methods yield the most information from sediments with contrasting properties such as composition, grain size, moisture content, density, or degree of consolidation. However, the severity of fracturing, which provides an indication of the ability of contaminants to migrate through the basalt, can be measured with geophysical techniques. This information would be useful when deciding whether a particular site is contributing contaminants to ground water.

Unsaturated zone monitoring is a method of investigation that is used to characterize the quality of water in the soil pores above the water table. The sample is collected in a lysimeter that is buried at some depth beneath the area of investigation. A lysimeter is a porous ceramic container with separate sampling vacuum hoses attached to it. Soil water is collected by evacuating the lysimeter

and then pressuring it to retrieve the sample. If the soil moisture content is low, up to several days may be required for soil water to seep into the lysimeter. Lysimeters are useful because they provide samples of downward infiltrating water before it reaches the water table. They can also be used to isolate sources of ground water contamination. Their usefulness at Mountain Home AFB is diminished because of the low soil moisture content.

## B. CONCLUSIONS

This section contains a summary of the conclusions reached after completion of Phase II, Stage 1. Recommendations for the next phase of IRP are given in the following paragraphs, and attendant costs are presented under separate cover in Appendix J.

Mountain Home AFB is located on the Mountain Home Plateau about 10 miles southwest of the city of Mountain Home. The Mountain Home Plateau is a rolling upland plain with occasional volcanic cones or buttes rising several tens to a few hundred feet above the plain. The plateau is underlain by over 10,000 feet of volcanic and sedimentary rock, of which the important formations are, in ascending order, the Idavada volcanics, the Glens Ferry Formation, and the Bruneau Formation. Ground water occurs in all of the formations underlying the plateau, although the principal source of ground water for the base is the Bruneau Formation.

Seventeen sites were identified within the base at which hazardous wastes were either handled or disposed of. The purpose of Phase II, Stage 1 was to investigate five of these sites selected through HARM rating in the Phase I study and to determine the extent of environmental contamination. The Phase II, Stage 1 field program consisted of soil sampling at three of the sites, installation and sampling of a monitor well at each of the remaining two sites, and the sampling of six base wells and two wastewater lagoons.

Evidence of organic ground water contamination was indicated by the analyses of samples from MW-1 and one base well. Of the inorganic parameters, only cadmium in the MW-1 sample exceeded the primary drinking water standard, although the absence of other trace metals suggests that the cadmium is from a natural source rather than from base activities. The well should be resampled and analyzed for cadmium. Concentrations of TOX were highest in the MW-1 and MH-3 samples (0.12 mg/L) and were relatively uniform in the remaining base well samples (0.055 to 0.086 mg/L). Although there are indications that the waste disposal areas are the sources of the organics, there also may be an off-base, upgradient source for the contaminants. The extent of contamination includes the western portion of the base, but the magnitude cannot be estimated without knowing the individual compounds

that contributed to the TOX concentrations and their corresponding health risks. TOC concentrations were too low to conclusively indicate either background or contaminated conditions. Traces of two pesticides were detected in the lagoon samples, along with high concentrations of TOX, suggesting that the lagoons or the former landfill underlying the lagoon may have a detrimental effect on the underlying ground water.

Evidence of soil contamination was found as deep as 10.5 feet beneath Site 8, which is the existing fire department training area. The most persistent contamination was found beneath the bermed area in which jet fuel is pooled before it is burned during the fire training exercises. The presence of contamination was shown by relatively high TOX and TOC concentrations. Samples from Borings DM-4 and DM-5, which were drilled outside the bermed areas, contained background concentrations of TOC and TOX at depths of 7.5 to 9 feet. However, evidence of contamination was present in the deepest sample from Boring DM-6, which was drilled inside the bermed area, and it is not possible to estimate how much deeper the contamination may extend.

TOX and TOC analyses of soil samples from Site 11 indicate that little, if any, contamination remains from the jet fuel that was spilled in the late 1950s. Shallow soil samples contained trace amounts of organic contaminants, although the low concentrations represent little or no significant contamination.

Site 12 is the entomology shop yard where pesticides and rinse water containing pesticides were drained. Of the 16 pesticides in the analyses, seven were detected in EP toxicity extractions from one or more soil samples at concentrations up to 2.4 µg/L, although most of the concentrations were less than 0.1 µg/L. Dieldrin and DDD were detected in most or all of the samples. The results of the pesticide analysis must be studied in light of the poor recoveries on spiked soil samples. Table B-2 in Appendix B shows recovery rates between 40 and less than 10 percent on the soil samples. These poor recovery rates indicate that pesticide concentrations may be an order of magnitude higher than those reported. These adjusted concentrations do not appear to cause any human health risk, because the original values are low.

The threat to human health posed by contaminants at Sites 8, 11, and 12 varies with each site. The health risk at Site 11 is insignificant because of the isolated location and low concentrations of contaminants in the soil. At Site 8, the health risk is low except when dusty conditions prevail, when exposure times amount to several hours, or when direct contact with site materials is necessary. The health risk at Site 12 is judged to be extremely low and insignificant.

## **VI. RECOMMENDATIONS**

The recommendations presented in this section have five primary purposes:

1. Identify those sites where further action is deemed warranted;
2. Confirm and identify the organic contaminants in ground water beneath the base;
3. Further investigate the depth of suspected soil contamination at Site 8;
4. Aid in identifying the sources of the contaminants; and
5. Verify cadmium results.

Various alternative measures for achieving these purposes, along with a detailed discussion of the information that would be obtained, are presented in Section V. The following are our recommendations for sites requiring no further action and sites warranting further investigation.

### **A. SITES WHERE FURTHER ACTIONS ARE DEEMED UNWARRANTED**

No indication of residual fuel was found in our investigation of Site 11. The actual amount of fuel that was lost is not known, nor is the percentage that washed away with surface flow. It has been indicated that as much spilled fuel as possible was pumped out of the area (CH2M Hill, 1983). In the 25 years or more since the fuel spillage and leakage occurred, it is probable that the last fuel has evaporated or decayed by biochemical transformation. It is highly unlikely that any fuel that entered basalt could now be found and recovered. Based on the results of sampling and analysis of soils, it is recommended that Site 11, the fuel hydrant system leak/spill area, not be considered for further actions.

The results of chemical analyses of EP toxicity test extracts of soil samples from Site 12, the entomology shop yard, have been analyzed taking into consideration the poor recoveries on spiked soil samples. The pesticide quantities are estimated to be in the range where there is little threat to human health. It is recommended that this site not be considered for further investigation.

### **B. SITES WARRANTING FURTHER INVESTIGATION**

It is recommended that an accurate water level survey of all the base wells and the two monitor wells be conducted in order to define the local ground water flow directions. To accomplish this, the monitor well elevations must be surveyed, and the depth to water in the base wells and monitor wells must be carefully measured and accurately converted to elevation. The resulting elevations will help

to evaluate the direction of migration of contaminants beneath the base and enable a more accurate placement of additional monitor wells and background wells. After completion of the survey, it is recommended that four monitor wells be installed at Site 1, one upgradient and three downgradient. The results of the water level survey should be studied to determine whether MW-2 at Site 2 was placed downgradient of the landfill. If MW-2 is downgradient of the landfill, no further action should be taken at this site. If MW-2 is determined to be upgradient of the landfill, three additional monitor wells should be installed downgradient. If it cannot be determined whether MW-2 is upgradient or downgradient, install one upgradient monitor well and three downgradient monitor wells as defined by the water level survey.

After installation of the monitor wells, it is recommended that ground water from the new wells, the two existing monitor wells (MW-1 and MW-2), operating base wells (MH-1, MH-3, and MH-5), and the two lagoons be resampled and analyzed for pH, specific conductance, major cations and anions, and the organic parameters in USEPA Methods 601 and 602 (Table 12). These parameters will characterize the organic content of the ground water and lagoon contents and will identify the compounds that contributed the organic halogens observed in the Phase II, Stage 1 analyses. Resampling is necessary to confirm the presence of organic contamination indicated by TOX concentrations in Phase II, Stage 1 and to identify the individual compounds that contributed to the TOX. Identification of the compounds will help to determine the source of the contaminants and to assess the health risk associated with the contaminants.

It is also recommended that the depth of the contamination indicated at Site 8, the existing fire department training area, be determined. The purpose of the additional borings is to determine whether the hazardous materials at the fire training area have migrated deep enough to constitute a potential source of contamination of the ground water. Two borings would be drilled within the bermed area, and soil samples would be collected at 2-foot intervals until a photoionization detector measures background levels of organic vapors emanating from the samples. To confirm the absence of organic contaminants, the deepest two samples from each of the borings would be analyzed for volatile and semi-volatile organics, oil and grease, and moisture content. To aid in interpreting the results from these two borings, a third boring would be drilled at the periphery of the fire training area, which has not been affected by activities at the site. The background boring would be drilled to the same depth as the bermed area borings, and four samples from various depths would be analyzed for volatile and semi-volatile organics, oil and grease, and moisture content.

Other alternatives discussed previously are not justified at present, in our opinion, and are not recommended at this time.

**REPORT OF WELL DRILLER**  
State of Idaho

State law requires that this report shall be filed with the State Reclamation Engineer within 30 days after completion or abandonment of the well.

**WELL OWNER:**

Name MT Home AFB #3

Address MT Home Idaho

Owner's Permit No. \_\_\_\_\_

NATURE OF WORK (check): ☐ Replacement well ☐

New well ☒ Deepened ☐ Abandoned ☐

Water is to be used for: domestic

METHOD OF CONSTRUCTION: Rotary ☐ Cable ☒

Dug ☐ Other \_\_\_\_\_

(explain)

CASING SCHEDULE: Threaded \_\_\_\_\_ Welded \_\_\_\_\_

8" Diam. from 0 ft. to 7 ft.

"Diam. from \_\_\_\_\_ ft. to \_\_\_\_\_ ft.

"Diam. from \_\_\_\_\_ ft. to \_\_\_\_\_ ft.

"Diam. from \_\_\_\_\_ ft. to \_\_\_\_\_ ft.

Thickness of casing: \_\_\_\_\_ Material: \_\_\_\_\_

Steel ☐ concrete ☐ wood ☐ other ☐

(explain)

PERFORATED? Yes ☐ No ☐ Type of

perforator used: \_\_\_\_\_

Size of perforations: \_\_\_\_\_ by \_\_\_\_\_

perforations from \_\_\_\_\_ ft. to \_\_\_\_\_ ft.

perforations from \_\_\_\_\_ ft. to \_\_\_\_\_ ft.

## WELL LOG

From Feet	To Feet	Type of Material	Drilling Time		Water-bearing Formation Yes No	Cased Pipe Yes No
			Hrs.	Min.		
204'	240'	Grey basalt				
240	247	Reddish grey basalt				
247	280	Grey basalt				
280	290	Stringers of reddish grey basalt and lava tuff?				
290	320	Grey basalt, extra large crevice at 293'				
320	326	Grey basalt, very hard				
326	338	Cemented red cinders				
338	378'6"	Grey basalt, creviced 340 to 351				
		" 364 to 378				

First water encountered at 342', static water level 309' 8"

Average speed of drilling was from 3' to 10' of crooked hole per day. In order to make straight hole it was necessary to use over one ton of dynamite to shoot the walls straight. Every known method of drilling straight hole with the use of cable tools was tried to no avail. All formation lay at a high angle with alternate layers of hard and softer material.

## WELL DRILLER'S REPORT

State law requires that this report be filed with the Director, Department of Water Resources within 10 days after the completion or abandonment of the study.

1 WELL OWNER  
Name PAUL STRASTERS  
Address MT HOME  
Owner Permit No. \_\_\_\_\_

7 WATER LEVEL  
Static water level: 345 feet below land surface  
Flowing? ☒ Yes ☐ No GPM flow \_\_\_\_\_  
Temperature \_\_\_\_\_ Quantity \_\_\_\_\_  
Artesian (closed in pressure) ☐ Yes ☐ No  
Controlled by valve 1.00 \_\_\_\_\_

2 NATURE OF WORK  
☒ New well ☐ Deepened ☐ Replacement  
☐ Abandoned (describe method of abandonment) \_\_\_\_\_

3 PROPOSED USE  
☐ Domestic ☐ Irrigation ☐ Test ☐ Other (specify type) \_\_\_\_\_  
☐ Municipal ☐ Industrial ☐ Stock ☐ Waste disposal or irrigation \_\_\_\_\_

4 METHOD DRILLED  
☐ Cable ☒ Surface ☐ Aug ☐ Other \_\_\_\_\_

5 WELL CONSTRUCTION  
Diameter of hole 6 inches Total depth 520 feet  
Lining schedule ☒ Steel ☐ Concrete  
Thickness 1/8 inches From 19 feet  
450 inches 6 inches feet feet  
19 inches feet feet  
19 inches feet feet  
19 inches feet feet  
19 inches feet feet  
Was casing drive shoe used? ☐ Yes ☒ No  
Was a packer or seal used? ☐ Yes ☒ No  
Perforating? ☐ Yes ☒ No  
How perforated? ☐ Factory ☐ Knife ☐ Torch  
Size of perforation \_\_\_\_\_ inches by \_\_\_\_\_ inches  
Number \_\_\_\_\_ From \_\_\_\_\_ To \_\_\_\_\_  
perforations \_\_\_\_\_ feet feet  
perforations \_\_\_\_\_ feet feet  
perforations \_\_\_\_\_ feet feet  
Well screen installed? ☐ Yes ☒ No  
Manufacturer's name \_\_\_\_\_  
Type \_\_\_\_\_ Model No. \_\_\_\_\_  
Diameter \_\_\_\_\_ Set from \_\_\_\_\_ feet to \_\_\_\_\_ feet  
Diameter \_\_\_\_\_ Set from \_\_\_\_\_ feet to \_\_\_\_\_ feet  
Gravel placed? ☐ Yes ☒ No Size of gravel \_\_\_\_\_  
Placed from \_\_\_\_\_ feet to \_\_\_\_\_ feet  
Surface seal depth 19 Material used is seal ☐ Cement grout ☒ Mud  
☒ Plugging clay ☐ Shot concrete  
Sealing procedure used ☐ Slurry seal ☐ Temporary surface casing ☒ Venturi to seal depth \_\_\_\_\_  
☒ Venturi to seal depth \_\_\_\_\_

this well was tested at 515'. I didn't  
produce much water. We drilled and 8" hole  
for culinary water then went back and  
deepened this one to 578'. This clay in the  
bottom is quite cavy. This well is to be  
tested again but hasn't been yet.

Drilling was stopped at 530 feet and well tested dry. Drilling was resumed and well was tested at 616 and was dry. Well was drilled to 625 feet where sand cavities have prevented deeper drilling without casing. Drilling was stopped February 28, 1967. Further drilling is anticipated later.

[A-52]

- L. H. [unclear]

I am talking with Mr. Clarence Calk who owns the property now and he says you didn't have a log on this well.

As I used G.O. Calk & Sons <sup>Weymouth, Mass.</sup> well log on this job I turned log in to them, and it has apparently gotten lost.

This well was drilled several times by Foyne Pump Co. out of Turn Falls, and I don't have the date cut for on this form.

Wonder if you could get Permit no. from your files?

I am real sorry about not having log in before now and if you need any further information, please let me know.

APPENDIX B

LABORATORY AND FIELD QUALITY CONTROL PROGRAMS

## APPENDIX B

### LABORATORY QUALITY CONTROL PROGRAM

UBTL is an accredited laboratory of the American Industrial Hygiene (AIHA) Association (No. 17) and, as such, participates in an extensive interlaboratory proficiency analytical testing program sponsored by the National Institute for Occupational Safety and Health (NIOSH). In addition, UBTL is currently licensed by the Center for Disease Control (CDC) to perform chemical and clinical analyses of biological specimens and is State of Utah/USEPA approved for environmental analyses. The comprehensive internal quality control program at UBTL is detailed as follows.

#### INTRODUCTION

UBTL has implemented an effective system for Quality Control (QC) for samples analyzed from Mountain Home AFB. Procedures that are employed include:

1. Services of a full-time Quality Control/Quality Assurance Section.
2. Preparation of internal quality control samples.
3. Collection and evaluation of quality control data.
4. Generation of quality control charts.
5. Instrument calibration and maintenance.

#### SAMPLE ANALYSES

At least one blank sample and one reagent blank are included with each set of analyses and processed through the complete analytical procedure in order to detect any contamination in either collection media or reagents. In addition, duplicate analyses are accomplished on a minimum of 10 percent of all samples submitted from the field. Internal quality control samples, generated in the laboratory and containing known quantities of specified analyte(s), are run at the rate of 10 percent of the total field sample workload. At the completion of the analysis of a sample set, each chemist calculates his results and reports the results on the Analytical Report Form. Results for replicated samples and internal quality control samples are reported on the computer-generated Quality Control Data Sheet. Before the results are submitted to the Group Leader, another peer chemist analyst is assigned to check results for possible errors in the calculations. He must approve results reported on both the quality control sheet and the sample sheet. The Group Leader, after his evaluation of the data, gives the report sheets to the Quality Assurance Specialist (QAS) for his evaluation and implementation of any required action.

Specific steps are followed when any one QC sample result is determined to be out of control in connection with the analysis of a field sample set. QC charts with adjusted control limits of  $\pm 3$  standard deviations will generally be used to determine whether a result is out of control. If QC results are in control, the QAS signs off the report. It is then reviewed by the Section Head for accuracy of the results. Upon final approval of the reports by the QAS and the Section Head, the reports are sent to the sponsor.

The paperwork containing the raw data for a sample set (i.e., chart paper, computer readouts, paper tapes, calibration curves, tables of data, etc.) is collected and placed in an 8½-inch by 11-inch envelope that has been labeled with sample numbers, analyst, date, and other pertinent information. The envelopes are filed by laboratory number for possible future reference and data retrieval. Raw data for each sample analysis are therefore readily available, if needed.

#### QUALITY CONTROL SAMPLE DATA ANALYSIS

A record of the preparation of internal QC samples is detailed in the QC log book maintained by the QAS. As appropriate, a set of QC samples is distributed to the chemist along with each sample set at an average rate of at least 10 percent of the submitted samples. The analyses and data evaluations are performed for these QC samples, along with the submitted samples, and results are tabulated on the computer-generated Quality Control Data Sheet. At least duplicate results are reported for each internal QC sample.

QC charts are generated for each analyte through the analysis of QC sample results. Each result is divided by the theoretical value to standardize results so that data from all concentrations can be directly compared for accuracy and precision. When a control data set of N sample results has been accumulated, the following statistics are calculated: mean percent recovery, replicate standard deviation, and set standard deviation. These statistics are then used to determine accuracy and precision QC limits.

The control data set is updated after evaluation of 20 successive QC samples and includes data on the 50 most recent results. Any control sample analysis that is beyond accuracy or precision limits is not used in the subsequent determination of new limits.

## EXTERNAL QUALITY CONTROL PROGRAMS

In addition to internally generated QC data, other information concerning QC is provided by the participation of UBTL in four interlaboratory QC programs: NIOSH Proficiency Analytical Testing (PAT) Program; two CDC Blood Lead QC Programs; and State of Utah Environmental Quality Control Program. The PAT Program and the CDC Blood Lead Programs involve the participation of more than 100 laboratories on a nationwide basis. The PAT Program addresses the analysis of filter samples for lead, cadmium, zinc, free silica, and asbestos and the analysis of charcoal tubes for various organic solvents.

## LABORATORY DATA REDUCTION

A significant fraction of the Chemistry Department's work involves data processing. Mathematical models, based upon analysis of standard solutions or samples, are generated in order to determine the quantity of analyte present in the samples. Considerable time and effort are saved by the utilization of automated data processing procedures. Data processing by the computer can include, for example, calculations, generation of standard calibration curves, mathematical modeling of standard curves, statistical analyses, and the generation of hard copy output. Advantages intrinsic to the use of an automated system include more accurate calculations, immediate and accurate generation of data plots, fewer transcription errors, and no calculation errors after programs have been verified and documented. In general, the types of data that are processed are those derived from the following techniques: atomic absorption and flame emission spectroscopy, gas and liquid chromatography, optical absorbance spectrophotometry, specific ion electrode, fluorescence spectroscopy, and wet chemistry determinations. Similar functions are employed for QC data. In addition, the data system is utilized to store QC data, provide statistical analyses, and generate and update QC charts. The advantage of the provision for statistical analyses and the production of QC charts by automation is that the charts may be easily updated with minimal effort. QC data and any required action may, therefore, be provided on a daily basis.

## REPORTING PROCEDURES

The analytical data are reported to the sponsor at the completion of each sample set. The report includes the following items:

1. A memorandum describing the sample set; the condition and appearance (i.e., homogeneity, integrity, etc.) of the samples upon receipt at UBTL; the method, equipment, and technique used in the determination; any interferences that were observed; and any unusual circumstances that may

have occurred during the analysis. [The limit(s) of detection are also reported.]

2. UBTL Analytical Report Form, including field ID number, laboratory ID number, identification of the analytes, results of each determination, limit(s) of detection, and comments.
3. Other items, such as copies of strip chart recorder output, computer printout sheets, and other raw data (to be included as required).

## **INSTRUMENTATION**

Each major equipment item at the UBTL Chemistry Department undergoes a routine preventive maintenance check on a regular schedule. This check is accomplished by a trained engineer. In addition, performance checks are made by the analyst prior to the analysis of each set of samples. This involves the analysis of one or more standards and a comparison of the values obtained with previous results and conditions. This information is recorded in an instrumentation log.

When an instrument or apparatus malfunctions and the problem is not readily corrected, the appropriate Section Head is notified. If it is determined that a visit by the service representative is required, a service call is scheduled and the QAS is notified. Action by the service representative is recorded by the QAS in the Instrument Maintenance Log, and the appropriate customer field and service order forms are filed, by instrument, in the Instrument Maintenance Log Supplement File. In an effort to monitor and maintain instrument specifications, logs for each of the AA spectrophotometers, the gas chromatographs (GC), the X-ray diffractometer (X-ray), and the mass spectrometers (MS) have been provided for the analytical chemists' use each time an analysis is performed. The AA instrumentation logs contain entries for date, analyst, lamp number (if more than one lamp is available), standard concentration (recommended in manual), reading in milliabsorbance units, and a column for when instrumental parameters differ from the recommended conditions listed in the manual. The GC, X-ray, and MS logs contain entries for date, time, analyst, set identification number, and comments on parameters or performance.

A comprehensive analytical chemistry equipment list is included at the end of this document.

## TRAINING

UBTL has established a continuing program of training of current personnel with respect to QC procedures. In addition, an intensive program for the training of recently recruited personnel in both analytical methods and techniques and QC policies has been implemented. It is the responsibility of the QAS and the Laboratory Director to train all laboratory personnel.

## RESULTS OF THE LABORATORY QC PROGRAM

The results of the QC analyses for ground water, surface water, and soil samples are presented in Tables B-1 and B-2.

### Ground Water and Surface Water QC Analyses

The laboratory QC program for ground water and surface water included analyses of spiked and duplicate samples and a method blank for each constituent. The samples used for QC analyses included the east and west lagoon, MH-1, NW-2 samples, and distilled water. In general, the spiked recoveries were satisfactory, ranging from 85 to 110 percent, except for the lagoon samples. Spiked recoveries in the lagoon samples ranged as low as 28 percent because of interference with bacteria in the water. When distilled water was substituted for the lagoon samples, the recoveries were satisfactory. The additional analysis of the spiked distilled water samples by the laboratory demonstrated that the method specified (EPA 608) was not effective in quantifying the pesticides in the lagoon water. Analyses of duplicate samples were also satisfactory. Traces of lead and cadmium were detected in the method blanks while analyzing the west lagoon and W-2 samples. The lead, chromium, and cadmium results for those two samples have been corrected for the concentrations found in the blanks.

### Soil QC Analyses

The laboratory QC program for soil samples included one or two spiked and duplicate samples and a method blank for each constituent. With the exception of the oil and grease and the pesticides, the spiked recoveries were between 87 and 110 percent. The oil and grease recovery of 125 percent was slightly higher than the accepted range. The pesticides showed recoveries of less than 10 percent when the spiked samples were analyzed using the specified method. Table B-2 shows that the laboratory analyzed additional spike samples using a sample leachate in order to show that the methodology was satisfactory. The additional testing showed recoveries in the range of 87 to 98 percent with the exception of p,p'-DDT, which was 146 percent. All of the duplicate analyses showed satisfactory reproducibility except lindane, in which there is a ten-fold difference between the duplicate

samples. None of the method blanks contained detectable concentrations of any of the constituents.

### FIELD INVESTIGATION QUALITY CONTROL PROGRAM

Quality control of field activities consists of following established procedures during the conduct of the work. In those cases that require the drilling of test borings, installation of piezometers or monitor wells, and taking of soil and water samples, the procedures include the preparation of records to document the compliance with these procedures. These field records include boring logs, monitor well installation records, daily field memoranda, sample shipment and test instruction forms for soil sample testing, and chain-of-custody records for all soil and water samples intended for chemical analyses. The nature of water sample tests was established in advance so that plans could be made to ship samples in an appropriate and timely manner.

The pH and specific conductivity meters used for field water quality measurements were calibrated with known standards immediately before the measurements were made. The HNU photoionization detector and explosimeter used to monitor vapors generated while drilling have internal calibration routines that were followed when the meters were turned on. A detailed description of sampling procedures is located in Section III.

KENNETH J. STIMPFL

**Title** Partner

**Expertise** Environmental Analysis  
Impact Assessment  
Site and Route Selection  
Aquatic Ecology

**Experience  
With Firm** Principal-in-Charge/Project Director

- Site selection and evaluation study for additions to existing fossil power plants, Michigan.
- Environmental assessment, permits and hearing for a new manufacturing plant in Michigan.
- Environmental baseline studies for a fossil-fueled power plant, Michigan.
- Environmental and geohydrological assessment of inactive industrial waste site, Michigan.
- Geohydrological assessment of chemically contaminated site, Michigan.
- Environmental assessment and defense in litigation for oil well development, Michigan.
- Environmental and engineering evaluation of manufacturing plant sites in Iowa, Indiana, Missouri, Michigan, Wisconsin, and Ontario.
- Ecological assessment of potential chemical contamination in the Menominee River, Wisconsin.
- Environmental assessment, preliminary containment design, and negotiation of consent judgment with state and federal agencies for a contaminated chemical plant site, Michigan.
- Site selection study for a new fossil or nuclear power plant, Michigan.
- Preparation of a regulatory compliance plan for a proposed synfuels project, Illinois.
- Radiation survey, assessment, decontamination and health physics monitoring for NRC release of contaminated plant site, Michigan.
- Wetland assessment, development of alternative layouts and agency negotiations regarding a denied 404 permit for a dock in Wisconsin.
- Assessment of environmental enhancement potential through selective dredging of the Little Calumet River for the Chicago District, Corps of Engineers.
- Assessment of potential economic impacts from a proposed regulation to ban landfill disposal of chlorinated solvents for the Illinois Department of Energy and Natural Resources.
- Assessment of aquatic impacts and effects on low-level hydroelectric potential for a variety of proposed dam modifications on the Fox River for the Chicago District, Corps of Engineers.

Project Manager

- Aquatic ecology baseline study and impact assessment for nuclear power plant in Wisconsin, Wisconsin Electric Power Company

**Dames & Moore**

- Environmental baseline studies and impact assessment for copper/zinc mine in Wisconsin, Exxon Minerals Company.
- Power plant site selection study.

**Past  
Experience**

Sargent & Lundy Engineers, Chicago, Illinois

- Power plant site selection and evaluation studies in Illinois, Iowa, Wisconsin, Indiana, and Oklahoma.
- Ecological baseline studies and impact assessments for thirteen fossil and nuclear power plants.
- Impact assessment, route selection and evaluation of alternative designs for transmission line in West Virginia.
- Evaluation of alternate cooling systems for nuclear power plant.

RICHARD L. JONES

Title            Project Hydrogeologist

Expertise        Ground Water Hydrology  
                  Geology

Experience       Project Hydrogeologist  
With Firm

- . Ground water contamination evaluations of copper mill tailings disposal facilities, including design of deep monitoring wells, direction of field data collection, and evaluations of contaminant control alternatives.
- . Geologic and hydrologic evaluations of proposed uranium tailings disposal systems and ground water contamination investigations of existing uranium tailings impoundments.
- . Investigations of hydrocarbon contamination of aquifers beneath major oil refineries, including monitoring well system design, assessment of the nature and extent of contamination, and design of oil recovery systems.
- . Evaluations of the quantity and rate of seepage from phosphate tailings impoundments.
- . Evaluation and design of dewatering systems.
- . Investigations of natural water seeps and design of seepage control facilities.
- . Hydrogeologic evaluation and design of industrial water supply wells.

Past  
Experience

- Project Manager/Senior Geologist, Engineering Enterprises
- . Hydrogeologic exploration, evaluation and well design of municipal industrial, and irrigation water supply systems.
  - . Evaluation and rehabilitation of existing municipal and irrigation water well fields.
  - . Evaluation and assistance in acquisition of water rights for municipal and irrigation well supplies.
  - . Application and development of computer aquifer models to evaluate and optimize well spacing, well construction and potential aquifer yields.
  - . Studies of ground water quality in both polluted and unpolluted aquifers.

STEVEN B. JOHNSON

Title                   Staff Hydrologist

Expertise             Ground Water Hydrology

Experience           As an assistant and staff hydrologist, STEVEN B. JOHNSON has been  
With Firm           responsible for the organization and analysis of ground and surface  
                      water data. As a principal investigator, he has conducted ground  
                      water contamination studies and operated in situ permeability ap-  
                      paratus. In addition, Mr. Johnson has contributed to the hydrologic  
                      analyses of siting, baseline, environmental, and final safety  
                      analysis reports for several large utilities. Some of his more  
                      pertinent experience is as follows:

- Hydrogeological investigation of industrial site, West Virginia.
- Ground water contamination study of industrial site, Michigan.
- In situ permeability study, Missouri.
- Fossil fuel power plant siting study, Wisconsin.
- Deep well sampling project, Wisconsin.
- Baseline ground water and surface water study for fossil fuel plant, Michigan.
- Baseline ground water study for nickel-zinc mine, Wisconsin.
- Nuclear final safety analysis report, ground water section, Kansas.
- Nuclear environmental report, ground water section, Kansas.
- Nuclear preliminary safety analysis report, geology section, Illinois.
- Ground water contamination study of industrial site, Ohio.
- Underground natural gas storage study, Illinois.
- Preparation of RCRA and Arizona hazardous waste permits.
- Site selection for fossil fuel power plant wastes, Wisconsin.
- Installation of ground water monitoring system for uranium tailings pond, Wyoming.
- Investigation of nitrate contamination of ground water, Oklahoma.
- Ground water investigation and RCRA compliance at refinery, New Mexico and Utah.
- Investigation of gasoline spill at service station, Utah.
- Investigation of seepage from fertilizer tailings pond, Utah.
- Conducted pumping tests at a proposed landfill site, Utah.

**Dames & Moore**

Academic 1975, B.A., Geology, Macalester College, St. Paul, Minnesota.  
Background 1977, M.S., Geology, Arizona State University, Tempe, Arizona.  
M.S. Thesis Topic: Delayed Yield in Unconfined Aquifers.

APPENDIX G

DAMES & MOORE HEALTH AND SAFETY PLAN

**DAMES & MOORE  
HEALTH AND SAFETY PLAN**

Project Name and Number: Phase IIb Environmental Investigation (01016-186-07)  
Project Site Location: Mountain Home Air Force Base, Idaho  
Project Manager: George Condrat  
On-Site Safety Officer:  
Plan Preparer: Michael W. Ander  
Plan Reviewer: Kim Petschek  
Preparation Date: February 7, 1984

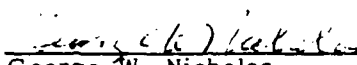

**Plan Approvals:**

Office Safety Coordinator

  
Michael W. Ander

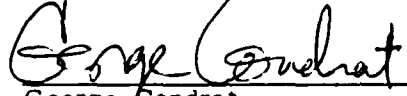

2/7/84  
(date)

Managing Principal-in-Charge

  
George W. Nicholas

2/5/84  
(date)

Project Manager

  
George Condrat

14 Feb 1984  
(date)

**I. PURPOSE**

The purpose of this Plan is to assign responsibilities, establish personnel protection standards, specify mandatory operating procedures, and provide for contingencies that may arise while operations are being conducted at the site.

**II. APPLICABILITY**

The provisions of the Plan are mandatory for all on-site Dames & Moore employees and subcontractors engaged in hazardous material management activities including but not limited to initial site reconnaissance, preliminary field investigations, mobilization, project operations, and demobilization.

### **III. RESPONSIBILITIES**

#### **A. Project Manager**

The PM shall direct on-site investigation and operational efforts. At the site, the PM, assisted by the on-site Safety Officer, has the primary responsibility for:

1. Assuring that appropriate personnel protective equipment is available and properly utilized by all on-site personnel.
2. Assuring that personnel are aware of the provisions of this plan, are instructed in the work practices necessary to ensure safety, and in planned procedures for dealing with emergencies.
3. Assuring that personnel are aware of the potential hazards associated with site operations (see Tables 1 and 2).
4. Monitoring the safety performance of all personnel to ensure that the required work practices are employed.
5. Correcting any work practices or conditions that may result in injury or exposure to hazardous substances.
6. Preparing any accident/incident reports (see attached Accident Report Form).
7. Assuring the completion of Plan Acceptance and Feedback forms attached herein.

#### **B. Project Personnel**

Project personnel involved in on-site investigations and operations are responsible for:

1. Taking all reasonable precautions to prevent injury to themselves and to their fellow employees.
2. Implementing Project Health and Safety Plans, and reporting to the PM for action any deviations from the anticipated conditions described in the Plan.
3. Performing only those tasks that they believe they can do safely, and immediately reporting any accidents and/or unsafe conditions to the PM.

#### IV. BACKGROUND

Based on preliminary site evaluations of the Mountain Home Air Force Base, there appear to be five (5) areas that may have generated significant environmental contamination over the lifetime of the facility. Although suspected contaminants have been identified, none has been quantified. However, we anticipate that only relatively low levels of contaminants will be encountered in the proposed drilling and soil and water sampling.

Site No. 1, designated as the Lagoon Landfill Site, served as a sanitary landfill for approximately 4 years, from 1952 to 1956. In 1961-62, two wastewater lagoons were built on top of the sanitary landfill. In addition to general refuse, the lagoon landfill has received POL (waste petroleum, oils, and lubricants) products at a rate of about 6 drums per month. Also, smaller amounts of trichloroethylene and carbon tetrachloride were placed in the landfill.

Site No. 2, the "B" Street Landfill, served as the main base landfill from 1956 until 1969. It accepted sanitary and industrial wastes including POL wastes and fly ash. In the early 1960s, JP-4 and AVGAS tank cleaning sludges were disposed here. Finally, 10 to 20 drums of DDT were buried here in 1969.

Site No. 8, the existing Fire Department Training Area, has been used since 1962. Practice fires were set on the ground by burning POL wastes, waste fuels, and commingled waste oils and solvents. Since 1975, only JP-4 has been used to fuel these fires, although some unauthorized dumping of POL wastes may have occurred after 1975.

Site No. 11, the Fuel Hydrant System Leak/Spill Area, is a location where two major fuel losses have occurred. The first, in the late 1950s, was a leak in an underground fuel transmission line that allowed approximately 50,000 gallons of AVGAS to escape. The second problem was a surface spill of about 14,000 gallons of AVGAS, also in the late 1950s. As a result of both spills, fuel saturation may still exist below the ground surface.

Site No. 12, the Entomology Shop Yard, is an area that has received wash water from pesticide application equipment; as a result, the soils have low concentrations of several pesticides, including DDT.

##### A. Dames & Moore Activity

Dames & Moore will drill soil borings at Sites 8, 11, and 12 and collect soil samples. Monitoring wells will be installed at Sites 1 and 2, and ground water samples will be collected. Water samples will also be collected from the lagoon at Site 1.

##### B. Suspected Hazards

Suspected hazards are presented above in as much detail as is currently available. These are: POL (waste petroleum, oils, and solvents) products, trichloroethylene, carbon tetrachloride, JP-4 fuel, AVGAS fuel, and pesticides (including DDT).

## V. EMERGENCY CONTACTS AND PROCEDURES

Should any situation or unplanned occurrence require outside or support services, the appropriate contact from the following list should be made:

Agency	Person to Contact		Telephone
D&M Project Manager	G. Condrat	(office)	801-521-9255
		(home)	801-943-3633
D&M Industrial Hygiene and Safety Director	K. Petschek	(office)	914-761-6323
		(home)	212-724-6414
Police			928-2256
Fire			117
Ambulance			828-2233
Hospital			828-6274
Command Post			828-2071
Crime Stop			828-6222

In the event that an emergency develops on site, the procedures delineated herein are to be immediately followed. Emergency conditions are considered to exist if:

- o Any member of the field crew is involved in an accident or experiences any adverse effects or symptoms of exposure while on scene.
- o A condition is discovered that suggests the existence of a situation more hazardous than anticipated.

The following emergency procedures should be followed:

- a. In the event that any member of the field crew experiences any adverse effects or symptoms of exposure while on scene, the entire field crew should immediately halt work and act according to the instructions provided by the Project Manager.
- b. The discovery of any condition that would suggest the existence of a situation more hazardous than anticipated should result in the evacuation of the field team and reevaluation of the hazard and the level of protection required.
- c. In the event that an accident occurs, the PM is to complete an Accident Report Form for submittal to the MPIC of the office, with a copy to the Health and Safety Program Office. The MPIC should assure that followup action is taken to correct the situation that caused the accident.

**VI. HAZARD CHARACTERISTICS, MONITORING METHODS, AND PROTECTION REQUIRED**

**Exposure Limits and Recognition Qualities**

Information concerning exposure limits and recognition qualities of the known contaminants that are suspected to be on site is presented in Table 1.

**Symptoms of Overexposure, Potential Chronic Effects and First Aid Treatment**

Symptoms of overexposure to the known suspected contaminants, potential chronic effects of these substances, and first aid treatment information are presented in Table 2.

**Monitoring Methods, Action Levels and Protective Measures**

Methods for monitoring for suspected contaminants, action levels, and protective measures to be used for various contaminant concentration levels are presented in Table 3.

**Protective Equipment Required for On-Site Activities**

The protective equipment required may vary, depending on the concentrations and dispersion of contaminants encountered during each phase of the work. Table 4 specifies protective equipment required for each on-site activity.

FORM #IHST-1  
REVIEW RECEIPT  
PROJECT HEALTH AND SAFETY PLAN

Instructions: This form is to be completed by each person to work on the site and returned to the Program Director-Industrial Hygiene and Safety.

Job No. 01016-186-07

Project: Mountain Home Air Force Base, Idaho

Rev. No. 0

Date 02/07/84

I represent that I have read and understand the contents of the above plan and agree to perform my work in accordance with it.

George W. Conrad  
Signed

14 Feb 1984  
Date

TABLE 1

## EXPOSURE LIMITS AND RECOGNITION QUALITIES

Compound	Exposure Standard <sup>a</sup>	IDLH <sup>b</sup> Level	Recognition Qualities		
			Color	Odor	State
CCl <sub>4</sub> (carbon tetrachloride)	5 ppm	300 ppm	Colorless	Ether-like odor	Liquid
DDT	1 mg/m <sup>3</sup>	N.A.	Colorless	Weak, chemical odor	Solid
TCE (trichloroethylene)	50 ppm	1000 ppm	Colorless	Soft, solventy, ethereal, chloroform-like	Gas

<sup>a</sup>OSHA permissible exposure limit or ACGIH Threshold Limit Value.<sup>b</sup>IDLH = immediately dangerous to life or health.

TABLE 2

## SYMPTOMS OF OVEREXPOSURE, POTENTIAL CHRONIC EFFECTS AND FIRST AID TREATMENT

Compound	Symptoms of Overexposure		Potential Chronic Effects
	Eye	Inhalation/Ingestion	
CCl <sub>4</sub>	---	Nausea, vomiting, dizziness, drowsiness, headache.	Liver and kidney damage, suspected liver carcinogen.
DDT	Irritation	Tingling of tongue, lips, and face, dizziness, headache, fatigue, convulsions, sense of apprehension, vomiting.	Suspected liver carcinogen.
TCE	Irritation	Drowsiness, dizziness, tremor, loss of coordination, mental confusion, vomiting, abdominal cramps.	Suspected carcinogen, liver and kidney damage, cardiac arrhythmias.

General First Aid Treatment

Eye	Irrigate immediately
Skin	Soap wash promptly
Inhalation	Move to fresh air
Ingestion	Get medical attention

TABLE 3

## HAZARD MONITORING METHOD, ACTION LEVELS, AND PROTECTIVE MEASURES

Hazard	Monitoring Method	Action Level	Protective Measures
Explosive atmosphere	Explosimeter or combustible gas meter	<10% LEL*	Continue working.
		10 - 25% LEL	Continue working with continuous monitoring.
		>25% LEL	EVACUATE the area; EXPLOSION HAZARD.
Toxic atmosphere	HNU continuous recorder	>5 units	Don respirator. See Table 1 for exposure standards.

\*Lower Explosive Limit (LEL) for ICE = 12.5%.

TABLE 4  
PROTECTIVE EQUIPMENT

Level	Protective Equipment	Criteria for Use
C	<p>Full-face respirator with air-purifying cartridges for gas/dusts</p> <p>Disposable coveralls</p> <p>Rubber boots</p> <p>Hard hat with splash shield or safety glasses/goggles</p> <p>Nitrile gloves</p>	<p>When drilling or sampling where dusts become airborne, when organic odors are noticeable, or as indicated by HNU.</p>
D	<p>Rubber boots</p> <p>Disposable coveralls (optional)</p> <p>Nitrile gloves</p> <p>Safety glasses or goggles</p> <p>Hard hat</p>	<p>During sampling activities other than those mentioned above</p>

ATTACHMENT 1  
PROTECTIVE EQUIPMENT

I. INTRODUCTION

When field investigation activities are conducted where atmospheric contamination is known or suspected to exist, where there is a potential for the generation of vapors or gases, or where direct contact with toxic substances may occur, equipment to protect personnel must be worn. Respirators are used to protect against inhalation and ingestion of atmospheric contaminants. Protective clothing is worn to protect against contact with and possible absorption of chemicals through the skin. In addition to protective clothing and respiratory protection, safe work practices must be followed. Good personal hygiene practice prevents ingestion of toxic materials.

Personnel equipment to be used has been divided into two categories commensurate with the degree of protection required, namely Levels C and D protection.

II. LEVELS OF PROTECTION

A. Level C

1. Personal Protective Equipment

- o Air-purifying respirator (MSHA/NIOSH approved)
- o Disposable chemical resistant coveralls
- o Gloves, outer, working gloves
- o Gloves, inner, chemical resistant
- o Boots, steel toe and shank
- o Hard hat (face shield)
- o Rubber boots, outer, chemical resistant (disposable)

2. Criteria for Selection

- a. Air concentrations of identified substances are such that reduction to at or below the substance's exposure limit is necessary and the concentration is within the service limit of the cartridge.
- b. Atmospheric contaminant concentrations do not exceed the Immediately Dangerous to Life or Health (IDLH) levels.
- c. Contaminant exposure to unprotected areas (head and neck) are within skin exposure guidelines, or dermal hazards do not exist.
- d. Job functions have been determined not to require a higher level of protection.

## **B. Level D**

### **1. Personal Protective Equipment**

- o Coveralls
- o Boots/shoes, safety or chemical resistant, steel toe and shank
- o Boots, outer (chemical resistant disposables)
- o Hard hat (face shield)
- o Gloves

### **2. Criteria for Selection**

- a. No indication of any atmospheric hazards.
- b. Work function precludes dusting, splashes, immersion, or potential for exposure to any chemicals.

### **3. Guidance on Selection Criteria**

- a. Level D protection is primarily a work uniform and should not be worn in any area where the potential for contamination exists.
- b. In situations where respiratory protection is not necessary, but site activities are needed, chemical resistant garments — high quality or disposable — must be worn.

## **III. RESPIRATORY PROTECTION**

The following procedures should be used for respiratory protection:

- A. Inspect all washers, diaphragms, and facepiece-to-face seal area for any tears, pinholes, deformation, or brittleness. Should any of these exist, use a different respirator.
- B. Place the respirator on the face, tighten and use both a positive and a negative pressure test, prior to entering the site, to assure a proper fit. Checking for proper fit involves the following:

### **1. Negative Pressure Test**

Close off the inlet opening of the cartridge or the breathing tube by covering it with the palm of the hand or by replacing the tap seal. Gently inhale so that the facepiece collapses slightly, and hold the breath for 10 seconds. If the facepiece remains in its slightly collapsed condition and no inward leakage of air is detected, the tightness of the respirator is satisfactory.

### **2. Positive Pressure Test**

Remove the exhalation valve cover. Close off the exhalation valve with the palm of the hand. Exhale gently so that a slight positive

pressure is built up in the facepiece. If no outward leakage of air is detected at the periphery of the facepiece, the face fit is satisfactory. (Note: With certain devices, removal of the exhaust valve cover is very difficult, making the test almost impossible to perform.)

## ATTACHMENT 2

### DAMES & MOORE STANDARD OPERATING PROCEDURES

#### WORK PRACTICES

1. Smoking, eating, drinking, and chewing tobacco are prohibited in the contaminated or potentially contaminated area.
2. Avoid contact with potentially contaminated substances. Do not walk through puddles, pools, mud, etc. Avoid, whenever possible, kneeling on the ground, leaning or sitting on equipment or ground. Do not place monitoring equipment on potentially contaminated surface (i.e., ground, etc.).
3. All field crew members should make use of their senses (all senses) to alert them to potentially dangerous situations (i.e., presence of strong and irritating or nauseating odors).
4. Prevent, to the extent possible, spillages. In the event that a spillage occurs, contain liquid if possible.
5. Prevent splashing of the contaminated materials.
6. Field crew members shall be familiar with the physical characteristics of investigations, including:
  - o wind direction
  - o accessibility to associates, equipment, vehicles
  - o communication
  - o hot zone (areas of known or suspected contamination)
  - o site access
  - o nearest water sources
7. The number of personnel and equipment in the contaminated area should be minimized consistent with site operations.
8. All wastes generated during D&M and/or subcontractor activities on site should be disposed of as directed by the Field Activity Leader.

## HALF-FACE RESPIRATORS

### INSPECTION PROCEDURE

1. Look for breaks or tears in the headband material. Also stretch to check the elasticity.
2. Make sure all headbands, fasteners, and adjusters are in place and not bent.
3. Check the facepiece for dirt, cracks, tears, or holes. The rubber should be flexible, not stiff.
4. Look at the shape of the facepiece for possible distortion that may occur if the respirator is not protected during storage.
5. Check the exhalation valve located near the chin between the cartridges by the following:
  - Unsnap the cover;
  - Lift the valve and inspect the seat and valve for cracks, tears, dirt, and distortion; and
  - Replace the cover. It should spin freely.
6. Check both inhalation valves (inside the cartridge holders). Look for same signs as above.
7. Check the yoke for cracks.
8. Make sure the cartridge holders are clean. Make sure the gaskets are in place and the threads are not worn. Also look for cracks and other damage.
9. Check the cartridges for dents or other damage, especially in the threaded part.

### DONNING PROCEDURE

1. Screw the cartridge into the holder hand-tight so there is a good seal with the gasket in the bottom of the holder, but don't force it. If the cartridge won't go in easily, back it out and try again.

Always use cartridges made by the same manufacturer who made the respirator.

2. Place the facepiece over the bridge of your nose and swing the bottom in so that it rests against your chin.
3. Hold the respirator in place and fasten the top strap over the crown of your head.

4. Fit the respirator on your face and fasten the strap around your neck. Don't twist the straps. Use the metal slide to tighten or loosen the fit, but not too tight.
5. Test the fit by:
  - Lightly covering the exhalation valve with the palm of your hand. Exhale. If there is a leak, you will feel the air on your face.
  - Covering the cartridges with the palms of your hands. Again, don't press too hard. Inhale. The facepiece should collapse against your face.
  - If there is a leak with either test, adjust the headbands or reposition the facepiece and test until no leakage is detected.

#### SANITIZING PROCEDURE

1. Remove all cartridges, plugs, or seals not affixed to their seats.
2. Remove elastic headbands.
3. Remove exhalation cover.
4. Remove speaking diaphragm or speaking diaphragm/exhalation valve assembly.
5. Remove inhalation valves.
6. Wash facepiece and breathing tube in cleaner/sanitizer powder mixed with warm water, preferably at 120° to 140°F. Wash components separately from the facemask, as necessary. Remove heavy soil from surfaces with a hand brush.
7. Remove all parts from the wash water and rinse twice in clean warm water.
8. Air dry parts in a designated clean area.
9. Wipe facepieces, valves, and seats with a damp lint-free cloth to remove any remaining soap or other foreign materials.

### Photoionization Detector

1. Before attaching the probe, check the function switch on the control panel to make sure it is in the off position.
2. Attach the probe by plugging in the 12 pin plug to the interface on the readout module.
3. Turn the six position function switch to the battery check position. The needle on the meter should read within or above the green battery arc on the scale. If not, recharge the battery. If the red indicator comes on, the battery should be recharged.
4. Turn the function switch to any range setting. Look into the end of the probe briefly to see if the lamp is on. If it is on, it will give a purple glow. Do not stare into the probe for any length of time as UV light can damage your eyes. The instrument is now ready for operation.
5. To zero the instrument, turn the function switch to the standby position and rotate the zero potentiometer until the meter reads zero. Clockwise rotation of the span pot produces a downscale deflection while counterclockwise rotations yields an upscale deflection. Note: No zero gas is needed since this is an electronic zero adjustment. If the span adjustment setting is changed after the zero is set, the zero should be rechecked and adjusted, if necessary. Wait 15 to 20 seconds to ensure that the zero reading is stable. If necessary, readjust the zero.
6. Turn function switch to the 0-20, 0-200, or 0-2000 position.
7. Place probe in the atmosphere to be monitored if the needle moves to the upper limit of the scale change the function switch to the next position.

## Combustible Gas Indicators (CGIs)/Explosimeters

In addition to the instructions found below, all CGIs should be calibrated prior to use, in a noncontaminated, fresh air environment. Furthermore, units incorporating an aspirator bulb or other air-drawing device should be checked for leaks in the following manner:

- Attach all hoses, probes, and other air-drawing devices to CGI
- Place a finger over probe or hose end.
- Operate pump or squeeze aspirator bulb.

In a leak-free system, bulb remains collapsed or pump labors. In a leaking system, bulb regains its shape or pump does not labor.

### a. MSA Explosimeter Combustible Gas Indicator

1. Turn Explosimeter on by lifting end of "On-Off" bar on "Rheostat" knob and rotating "Rheostat" knob clockwise 1/4 turn.
2. Flush instrument with fresh air by squeezing and releasing aspirator bulb about five times.
3. Rotate "Rheostat" knob until meter needle rests at zero. (Avoid large clockwise rotation, which sends large current through filament, perhaps shortening its useful life).
4. To sample, place hose or probe end in atmosphere to be measured and operate aspirator bulb about five times.

5. Read percent of lower explosive limit (LEL) as meter needle fluctuates from a steady-state level to a higher level each time the aspirator bulb is flexed. The steady-state reading indicates the "true" value.
6. Turn Explosimeter off by lifting end of "On-Off" bar on "Rheostat" knob and rotating it counterclockwise until it "clicks". "On-off" bar retracts into "Rheostat" knob.

b. Bacharach Oxygen/Combustible Gas Indicator, Model GPK

1. Rotate "Function" switch clockwise to "Volt Test" position. To avoid decalibration, all knobs must be pulled and rotated at the same time. Motor starts and the "% Oxygen" and "Sniffer" move up scale.
2. Rotate "Volt Adj" knob to bring "Gas Detector" needle over green arrow.
3. Turn "Function" switch clockwise to "On". The "% Oxygen" needle should rise to about 20.8% and "Gas Detector" needle should drop to about zero.
4. Rotate "Oxy Cal" knob to adjust "% Oxygen" needle to black "Calibrate" line.
5. Rotate "Zero Adj" knob to adjust "Gas Detector" needle to zero.
6. Momentarily place finger over hose or thread "Air Intake" nipple and observe the pump working.
7. To sample, place hose end and probe in atmosphere to be measured. Within 30 seconds, steady-state readings are indicated on "% Oxygen" and "Gas Detector" scales.
8. Rotate "Function" switch counterclockwise to "Off".

APPENDIX H  
SCOPE OF WORK

INSTALLATION RESTORATION PROGRAM  
PHASE II TASK DESCRIPTION  
MOUNTAIN HOME AFB ID

I. DESCRIPTION OF WORK

The purpose of this task is to determine if environmental contamination has resulted from waste disposal practices, fuel spills, pesticide contamination and fire training activities at Mt Home AFB ID; to provide estimates of the magnitude and extent of contamination, should contamination be found; to identify potential environmental consequences of migrating pollutants; to identify any additional investigations and their attendant costs necessary to identify the magnitude, extent and direction of movement of discovered contaminants.

Ambient air monitoring of hazardous and/or toxic material for the protection of contractor and Air Force personnel shall be accomplished when necessary, especially during the drilling operation.

The presurvey report (mailed under separate cover) and Phase I IRP report (mailed under separate cover) incorporated background and description of the sites for this task. To accomplish the survey effort, the contractor shall take the following steps:

A. General

1. Collect and analyze one sample from each of the existing wells (production or otherwise). A maximum of 6 wells shall be sampled. If the well(s) cannot be sampled due to well development, well characteristics (and or other reason), the contractor shall indicate the reason(s) in the report specified in Item VI below.

a. The U.S. Air Force shall provide to the contractor well logs and other pertinent wells records and information to determine that samples collected are representative.

b. All water samples collected in A.1. above shall analyzed for oil and grease IR Method (EPA Method 413.2), total organic carbons (EPA Method 415.1) and total organic halogens (EPA Method 9020). Required detection limits for above analysis are specified in Atch 1.

2. The areal extent of each site shall be determined by reviewing available aerial photos of the base, and by field reconnaissance.

3. Each location where surface water, sediment, or core samples are collected shall be marked with a permanent marker (where practical), and the location recorded on a project map for the site.

4. All the water samples collected from each well and the lagoon locations shall be analyzed on site for pH, temperature, and specific conductance. Sampling, maximum holding time, and preservation of the samples will strictly comply with the following references: Standard Methods for the Examination of Water and Wastewater, 15th Ed. (1980); ASTM, Part 31 (1980); and methods for Chemical Analysis of Water and Wastes, EPA Manual 600/4-79-020 (1979).

5. All the water and soil samples shall be analyzed in the laboratory for the parameters specified by site in Atch 2. Minimum detection limits for analyses are shown in Attachment 1.

B. In addition to items delineated in A above, conduct the following specific actions at the following identified sites:

1. Lagoon Landfill (Site 1)

a. Complete and sample a monitor well to the main water table below the site. Drill to a depth of about 50 feet below the water table and screen from about 10 feet above the water table to the bottom of the well, with an estimated depth to be approximately 450 feet. The upper 50 feet of the initial boring shall be grouted and cased prior to drilling below that level. It is proposed to drill a 12-inch hole to 50 feet, set 8-5/8 inch OD steel casing to 50 feet, and grout to the ground surface. The grout shall consist of neat cement or sand-cement with the addition of up to 4 percent bentonite. If severe formation losses occur, lost circulation materials or bentonite shall be used for the remaining grouting. After the grout has set, an 8-inch hole shall be advanced to the total depth of the well. A four-inch diameter, flush-threaded Schedule 80 PVC blank pipe and PVC saw-cut screen shall then be lowered into the well. The plastic casing and screen shall be joined with threaded joints, and no adhesive compounds or solvents will be used. A sand pack shall then be tremied into place around the annulus of the screen. The sand pack material shall consist of a clean, washed quartzose sand. Three feet of bentonite pellets shall then be placed on the 8-inch diameter steel pipe to protect the inner PVC casing. The well shall be cleaned and developed by pumping or bailing.

b. A geologic log shall be prepared for the boring based upon cutting samples and drilling characteristics.

c. One water sample shall be collected from the well. A minimum of three times the volume of standing water in the well shall be removed prior to taking samples. The static water level in the well shall be measured.

d. One water sample shall be collected from sewage lagoon 2.

2. B Street Landfill (Site 2)

a. Drill a single well to the main water table near the southern perimeter of the B Street Landfill. The work effort shall be as defined in I.B.1 (Site 1) above.

INSTALLATION RESTORATION PROGRAM PHASE II  
CONFIRMATION/QUANTIFICATION STAGE I(U) DAMES AND MOORE  
PARK RIDGE IL 24 FEB 86 F33615-83-D-4002

3/3

UNCLASSIFIED

F/G 13/2

NL

b. Collect one ground water sample.

3. Existing Fire Dept Training Area (Site 8)

a. Drill and sample three borings to depths of 10 feet or refusal, whichever is shallower, using hollow stem auger techniques.

b. Samples shall be taken utilizing split spoon sampling techniques at intervals of approximately 18 inches from the ground surface to the total depth of the boring.

c. Upon completion, each borehole shall be backfilled with granular bentonite to within 1 foot of the ground surface. The upper 1 foot of borehole shall be backfilled with natural soil.

d. Based upon visual inspection and HNU readings, two samples from each boring, one in the upper half of the boring and one in the lower portion, shall be selected for laboratory analysis.

e. All soil samples shall be shipped under refrigeration to the chemical laboratory for possible subsequent analysis. Soil samples not selected for analysis shall be frozen and archived for a period of 6 months. Soil samples shall be analyzed for the parameters listed in Atch 2.

4. Fuel Hydrant System Leak/Spill Area (Site 11)

a. Drill and sample three borings to depth of 10 feet or refusal, whichever is shallower, using hollow auger techniques. The work effort shall be as defined in I.B.3. (Site 8) above.

b. All borings shall be drilled into soil southwest of the aircraft apron.

5. Entomology Shop Yard (Site 12)

a. Drill and sample three shallow borings to depths of approximately 5 feet.

b. Obtain two soil samples from each boring over the intervals of 0 to 0.5 foot in depth and 1.0 to 1.5 feet in depth.

c. Obtain additional soil samples at depths of 3 and 5 feet.

d. The borings shall be located at 10, 20, and 30 feet from the northwest wall of the Entomology Shop building.

e. Two shallow soil samples (over the intervals of 0-0.5 feet and 1.0-1.5 feet) from each boring shall be analyzed for pesticides as listed in Atch 1.

f. The two deeper samples (at depths of 3 and 5 feet) from each hole will be stored for potential future analysis.

#### C. Well Installation and Cleanup

The well and boring area shall be cleaned following the completion of each well or boring. Drill cuttings shall be removed and the general area cleaned. If hazardous waste is generated in the process of well installation the contractor shall be responsible for proper containerization (according to local Civil Engineering Office requirements) for eventual government disposal. Disposal of drill cuttings are not the responsibility of the contractor. the well. Drill cuttings shall be removed and the general area cleaned.

#### D. Data Review

Results of sampling and analysis shall be tabulated and incorporated in the Informal Technical Information report (Atch 1, Seq 3 and Atch 3, Seq 2 as specified in VI below) and forwarded to USAF OEHL/CVT for review.

#### E. Report Preparation

1. A draft final report delineating the findings of this field investigation shall be prepared and forwarded to the USAF OEHL as specified in Item VI below. The report shall include a discussion of the regional hydrogeology, well logs of all project wells, data from water level surveys, water quality analysis results, available geohydrologic cross sections, groundwater surface and gradient vector maps, vertical and horizontal flow vectors and Laboratory quality assurance information. The report shall follow the USAF OEHL supplied format (mailed under separate cover).

2. Estimates shall be made of the magnitude, extent and direction of movement of contaminants discovered. Potential environmental consequences of discovered contamination must be identified. Where survey data are insufficient to properly determine or estimate the magnitude, extent and direction of movement of discovered contaminants, specific recommendations, fully justified, shall be made for additional efforts required to properly evaluate contamination migration and included in a separately bound appendix to the draft final report (see F below).

#### F. Cost Estimates

The contractor shall provide estimates for all additional work recommended to permit proper determination of contaminants. The recommendations provided shall include all efforts required to determine the magnitude and direction of movement of discovered contaminants along with an estimate of the time required to accomplish the proposed effort. This information shall be provided in a separately bound appendix to the draft final report.

### II. SITE LOCATION AND DATES:

Mt Home AFB ID  
Building, Time and Dates to be established

### III. BASE SUPPORT: None

IV. GOVERNMENT FURNISHED PROPERTY: None

V. GOVERNMENT POINTS OF CONTACT:

VI. In addition to sequence numbers 1, 5 and 10 listed in Atch 1 to the contract, which are applicable to all orders, the reference numbers below are applicable to this order. Also shown are data applicable to this order.

Sequence No.	Block 10	Block 11	Block 12	Block 13	Block 14
Atch 1					
4	ONE/R	5.5 MAC	6 MAC	9 MAC	*
3	ONE/T	**	**		
Atch 3					
2	ONE/T	**	**		

\*A minimum of two draft reports will be required. After incorporating Air Force comments concerning the first draft report, the contractor shall supply the USAF OEHL with a second draft report. The report shall be forwarded to the applicable regulatory agencies for their comments. Contractor shall supply the USAF OEHL with 25 copies of each draft report and 50 copies plus the original camera ready copy of the final report.

\*\*Upon completion of analysis.

VII. The ceiling price of Items 0001 and 0002, as contemplated by the payments clause, is \$

RECOMMENDED LEVELS OF DETECTION (PER USAF OEHL/SA)  
(19 Aug 1983)

GENERAL ORGANICS: Detection limits are for water unless shown otherwise:

ORGANIC ANALYTE	DETECTION LIMIT (µg/L)
Chemical Oxygen Demand	5000
Hydrazine	10
Oil and Grease (IR)	100 (100 µg/g, soil)
Polychlorinated Biphenyls	0.25 (1 µg/g, soil*)
Phenol	1
*** Total Organic Carbons(TOC)	1000
*** Total Organic Halogen(TOX)	5 (5 µg/g, soil)
Volatile Organic Compounds(VOC)	**

\*Identify type if possible.

\*\*Per EPA Method 503.1, 601 and 602. Report in µg/g for soils.

\*\*\*Detection levels for TOC and TOX must be 3 times the noise level of the instrument. Laboratory distilled water must show no response. If so, corrections of positive results must be made.

INORGANICS: Detection limits are for water unless shown otherwise:

INORGANIC ANALYTE	DETECTION LIMIT (µg/L)
Arsenic	10
Boron	100
Cadmium	10
Chloride	1000
Copper	50
Chromium	50 (5 µg/g, soil)
Cyanide	10
Iron (total)	100
Lead	20 (2 µg/g, soil)
Manganese	50
Mercury	1
Nickel	100
Nitrates	100
Silver	10
Sodium	1000
Specific Conductance	1*
Sulfate	1000
Total Dissolved Solids	1000
Zinc	50

\*Concentration is in micromhos

PESTICIDES: Analyze samples for chlorinated hydrocarbon and organophosphate pesticides. Detection limits are for water unless shown otherwise:

PESTICIDE ANALYTE	CONC (µg/L)
Aldrin	0.02
DDT isomer	0.02
Dieldrin	0.02
Endrin	0.02
Heptachlor	0.02
Heptachlor epoxide	0.02
Lindane	0.01
Methoxychlor	0.20
Diazinon	0.02
Malathion	0.10
Parathion	0.02
Toxaphene	1.00
2,4-D	0.06
2,4,5-T	0.06
2,4,5-TP silvex	0.06
Chlordane	0.20
alpha-BHC	0.02
beta-BHC	0.02
delta-BHC	0.02

For soils, use the detection levels shown above, but report values as micrograms pesticide per gram of soil.

TABLE 1

## PROPOSED PHASE IIb ANALYSES

	FIELD MEASUREMENTS <sup>a</sup>	TOX, TOC, AND OIL AND GREASE	HEAVY METALS	PHENOLS	PESTICIDES <sup>b</sup>	REMARKS
Surface Water Sampling						
Lagoon Landfill (Site 1) and Sewage Lagoon 2	X	X	X <sup>c</sup>	X	X	2 samples
Monitoring Wells						
Lagoon Landfill (Site 1)	X	X	X <sup>c</sup>	X	X	1 sample
B Street Landfill (Site 2)	X	X	X <sup>c</sup>	X	X	1 sample
Soil Sampling						
Existing Fire Department Training Area (Site 8)		X	X <sup>d</sup>	X		6 samples (3 locations, 2 depths)
Fire Hydrant System Leak/Spill Area (Site 11)		X	X <sup>d</sup>			6 samples (3 locations, 2 depths)
Entomology Shop Yard (Site 12)					X <sup>e</sup>	6 samples (3 locations, 2 depths)

<sup>a</sup>Field measurements consist of pH, temperature, and conductivity.

<sup>b</sup>Pesticides consist of aldrin, DDD, DDE, dieldrin, endrin, heptachlor, heptachlor epoxide, lindane, DDT, methoxychlor, chlordane, alpha-BHC, beta-BHC, delta-BHC, and toxaphene.

<sup>c</sup>The following heavy metals will be analyzed: lead, nickel, chromium, cadmium, and silver.

<sup>d</sup>Total lead only, by nitric acid digestion.

<sup>e</sup>EP toxicity extraction.

APPENDIX I  
DEFINITIONS, NOMENCLATURE, AND UNITS OF MEASUREMENT

## APPENDIX I

### DEFINITIONS, NOMENCLATURE, AND UNITS OF MEASUREMENT

<b>ac-ft/yr</b>	Acre-feet per year
<b>AFB</b>	Air Force Base
<b>alluvium</b>	Unconsolidated sediments deposited during comparatively recent geologic time by a stream or other body of running water.
<b>aquifer</b>	A geologic formation, group of formations, or part of a formation that is capable of yielding water to a well or spring.
<b>aromatic</b>	Designating cyclic organic compounds characterized by a high degree of stability in spite of their apparent unsaturated bonds and best exemplified by benzene and related structures, but also evident in other compounds.
<b>artesian</b>	Ground water confined under hydrostatic pressure.
<b>as N</b>	As weight of nitrogen
<b>AVGAS</b>	Aviation gasoline
<b>caliche</b>	An opaque, reddish brown to buff or white calcareous material of secondary accumulation (in place), commonly found in layers on, near, or within the surface of stony soils of arid and semiarid regions, but also occurring as a subsoil deposit in subhumid climates. The cementing material is essentially calcium carbonate, but may contain magnesium carbonate, silica, or gypsum.
<b>CGWA</b>	Critical ground water area
<b>cm/sec</b>	Centimeter(s) per second
<b>DEQPPM</b>	Defense Environmental Quality Program Policy Memorandum
<b>DOD</b>	Department of Defense
<b>downgradient</b>	In the direction of decreasing hydraulic static head; the direction in which ground water flows.
<b>effluent</b>	A liquid waste discharge from a manufacturing or treatment process, in its natural state, or partially or completely treated, that discharges into the environment.
<b>°F</b>	Degrees Fahrenheit
<b>ft</b>	Foot, feet

<b>gpd/ft</b>	Gallon(s) per day per foot
<b>gpm</b>	Gallon(s) per minute
<b>gpm/ft</b>	Gallon(s) per minute per foot of drawdown
<b>HNU</b>	A type of photoionization detector for measurement of organic vapors
<b>hydraulic gradient</b>	In an aquifer, the rate of change of pressure head per unit of distance of flow at a given point and in a given direction.
<b>in.</b>	Inch, inches
<b>IRP</b>	Installation Restoration Program
<b>mg/g</b>	Milligram(s) per gram
<b>mg/L</b>	Milligram(s) per liter
<b>ml</b>	Milliliter(s)
<b>µg/g</b>	Microgram(s) per gram
<b>µg/L</b>	Microgram(s) per liter
<b>MOGAS</b>	Motor gasoline
<b>monitor well</b>	A well used to measure ground water levels and to obtain samples.
<b>No.</b>	Number
<b>NPDES</b>	National Pollutant Discharge Elimination System
<b>OEHL</b>	Occupational and Environmental Health Laboratory
<b>pH</b>	Negative logarithm of hydrogen ion concentration; measurement of acids and bases.
<b>PDWS</b>	Primary drinking water standard(s)
<b>percolation</b>	Movement of moisture by gravity or hydrostatic pressure through interstices of unsaturated rock or soil.
<b>permeability</b>	The property or capacity of a porous rock, sediment, or soil for transmitting a fluid without impairment of the structure of the medium; it is a measure of the relative ease of fluid flow under unequal pressure.
<b>phenols</b>	Any of various acidic compounds analogous to phenol and regarded as hydroxyl derivatives of aromatic hydrocarbons.

<b>Pleistocene</b>	An epoch of geologic time thought to have covered the span between 1.6 million and 10,000 years ago.
<b>POL</b>	Petroleum, oil and lubricants
<b>porosity</b>	The property of a rock, soil, or other material of containing interstices.
<b>potentiometric surface</b>	An imaginary surface representing the static head of ground water and defined by the level to which water will rise in a well.
<b>Precambrian age</b>	Geologic time before the beginning of the Paleozoic; it is equivalent to about 90 percent of geologic time and ended approximately 570 million years ago.
<b>PVC</b>	Polyvinyl chloride
<b>QC</b>	Quality control
<b>RCRA</b>	Resource Conservation and Recovery Act
<b>specific capacity</b>	The rate of discharge of a water well per unit of drawdown, commonly expressed as gallons per minute per foot.
<b>specific conductivity</b>	With reference to the movement of water in soil, a factor expressing the volume of transported water per unit of time in a given area.
<b>STP</b>	Sewage treatment plant
<b>TAC</b>	Tactical Air Command
<b>TDS</b>	Total dissolved solids
<b>Tertiary</b>	The first period of the Cenozoic era, thought to have covered the span of time between 66 and 3 to 2 million years ago.
<b>TOC</b>	Total organic carbon
<b>TOX</b>	Total organic halogens
<b>transmissivity</b>	The rate at which water is transmitted through a unit width under a unit hydraulic gradient.
<b>USAF</b>	United States Air Force
<b>USEPA</b>	United States Environmental Protection Agency
<b>USGS</b>	United States Geological Survey
<b>water table</b>	That surface of a body of unconfined ground water at which the pressure is equal to that of the atmosphere.

END

DTIC
